LKB ANNOUNCES MORE.

MORE CONVENIENCE

New pre-blended Ampholine[®] carrier ampholytes for electrofocusing are available in three narrow and one wide pH range. Now there's no need to spend time mixing to achieve these specific ranges. Just select the pre-blended Ampholine you need (pH 2.5 to 4.5, 4.0 to 6.5, 5.0 to 8.0 and 3.5 to 9.5). They're designed to give the same linear, virtually drift-free pH gradient achieved using standard Ampholine with LKB Agarose-EF or acrylamide gels.

MORE POWER

The new Model 2197 Power Supply for electrofocusing and electrophoresis offers top-of-the-line features at a very affordable price. The Model 2197 delivers up to 2500V for high-resolution electrofocusing and its 250mA output makes it useful for other electrophoretic techniques. Choose constant power/constant voltage/constant current/time control modes to suit your application. Automatic crossover between running modes compensates for varying gel conditions. Built-in timer with alarm and automatic shutoff allows for time control. With accurate control of four parameters, you can achieve maximum resolution and reproducibility in all your electrofocusing and electrophoresis experiments. Bright LED display lets you monitor performance easily and the Model 2197 is designed to comply with all relevant safety standards.

MORE ECONOMY

LKB's new capillary gel casting system easily produces gels only one quarter the thickness of standard ones. You save substantially on reagent use and you'll be able to employ higher voltage for decreased run times because the new thinner gels dissipate heat more efficiently. The capillary gel casting kit works with agarose and acrylamide gels. Combine it with the new pre-blended Ampholine and the 2500 volt power supply to significantly reduce your run times while cutting costs. Ask your local LKB representative for more information on these new products and the complete line of LKB instruments and consumables. Depend on the leader in electrofocusing to give you more.

GUIDE TO AUTHORS

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusion in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should be identified in the margin on their first appearance. Equations should occupy single lines if possible: $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on halftones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

LIGHT MICROSCOPY '81 — THE STATE OF THE ART

International Conference and Exhibition on Light Microscopy

Imperial College, London SW7 7-9 July, 1981

The Exhibition, is organised by the Royal Microscopical Society in association with 'Nature'.

The Conference not only marks the inauguration of the Light Microscopy Section of the Royal Microscopical Society, but establishes a landmark in the field by providing a definitive statement of the more important aspects of light microscopy as it is now and of significant developments.

The first day's programme is devoted to the instrument itself. The second day is concerned with imaging techniques, and "light" microscopy is interpreted liberally. The third day will deal with two aspects of measurements on images — photometric (in transmission, emission and reflection) and geometric.

A trade exhibition will be held in conjunction with the meeting. In it, manufacturers will show equipment at the forefront of development and pertinent to the meeting programme. The exhibition will be open, *free of charge*, to both meeting registrants and non-registrants. Times when non-registrants may visit the exhibition are given below. (A registration form is inserted in this Journal.)

PROVISIONAL PROGRAMME

G. Bonino, P.P. Lombardini, A. Longhetto and P. Trivero	Radio acoustic measurement of fog-capping thermal inversions	121	A.G. Baer	Two orogenies in the Grenville Belt?	129

Cover: The three textures on the cover appear very distinct even though they have identical third-order statistics and thus identical second-order statistics and Fourier power spectra. Experiments reviewed on pages 91 to 97 show that 'instantaneous' texture discrimination cannot be explained solely in terms of global properties of the texture and that discrimination is the result of local, conspicuous features.

CURRENT CONTENTS: INDISPENSABLE!

CURRENT CONTENTS...

the best way to keep up with new
developments in your field—while
they're still new!

"By way of comment on Current Contents...your publication is indispensable around here. It comes back from circulation battered and torn -- obviously well used -- and people request references from journals we could never hope to subscribe to. Through Current Contents our library's collection is virtually unlimited.

Regarding OATS, since Current Contents generates so many reference requests, I find that OATS is really a time saver. I don't have to spend a lot of time and effort trying to locate a source for some of the more exotic titles you include in CC."

Mary Jane Campbell

Mary Jane Campbell, Librarian
Ferro Chemical
7040 Krick Road
Bedford, Ohio 44146

Current Contents, the world's most widely-used literature alerting service, displays tables of contents of the most recent issues of over 1,000 important journals and more than 700 multi-authored books. Every week top journals from all over the world are covered. . .giving you precise, but easy access to the articles you need to keep abreast of the latest developments in your field.

Current Contents also gives you several alternative ways to obtain any article quickly and easily if your library doesn't carry the journal. You can use *CC*'s Author Address Directory to write to the author for a reprint. Or if the article is needed immediately, you can request it from ISI's OATS® (Original Article Tear Sheet) service. For a minimal fee, OATS will have

a copy of the article in the mail to you within 24 hours after receipt of your request. You can then use the record of article requests which originated from *CC* to determine which journals you might want to subscribe to. . .or might ask your library to subscribe to. Over 300,000 researchers, scientists, and teachers rely on *CC*, coupled with OATS, to provide the journal coverage they need.

But don't just take our word for it. Why not send for a free copy of *CC* and see how it will enable you to keep up with new developments in your field — while they're still new. You have seven broad disciplinary areas from which to choose. To order your *free* issue — simply use the coupon below.

Please send me a free copy of the *Current Contents*® edition(s) I've checked below. I understand there is no cost or obligation.

MICRO-gTM VIBRATION ISOLATORS

- New standards of performance
- New, exclusive isolators
- Sensible prices

IMPROVED SMALL TABLES

MICRO-g air isolation tables have always given exceptional performance at a good price. Now, a number of engineering improvements have been made "standard" and have increased vibration isolation significantly... about 40% better in the low frequency range where it's hard to improve any small isolator. Or, you can specify our new, optional Gimbal Piston (see below) for the best isolation in any small table system. Other improvements include stiffer, deader laminated stainless steel tops and a growing diversity of modular isolator frames that assure an available solution for your special problems.

BASE-MOUNT PLATFORMS AND SPECIAL MODULES

Our exclusive, integrated, damped platform-and-isolator design solves the problem of isolating ungainly instrument consoles and large test systems with high centers of gravity. Micro-circuitry mask aligners, electron microscopes, precision measuring systems, and extra-sensitive vacuum systems are among the proven uses. Also, specially designed isolator modules can be made to fit your exact requirements for new installations, or to replace ineffective shock mounts or cumbersome structures.

TM-5

LARGE TABLE ISOLATORS

MICRO-g pedestal isolators are the answer to isolating large research tables. If you have an existing top, tell us the size and weight and we'll provide the correct isolators. Or, we can supply everything, including a granite plate or structured steel top, at competitive prices. Standard isolator components will handle loads from a few hundred pounds to several tons.

ADVANCED, GIMBAL PISTON* WITH HORIZONTAL ISOLATION

The thin-wall diaphragm isolator element, such as we use, has always been best for vertical isolation. Now, we've developed a way to make it virtually as effective in the horizontal mode as the vertical. It's a new type isolator called the TMC Gimbal Piston*. It handles horizontal inputs with an effectiveness derived from its superb vertical characteristics. It is entirely stable, with no sideways lean tendencies, and does not depend on the length of a hanging rod, wire or counter-mass for its frequency characteristics. The TMC Gimbal Piston is optional on all sizes of MICRO-g isolators. It is simply the best isolator we've ever measured.

PRODUCT REVIEW This week's product review on p. xxxv covers products on view at the FASEB exhibition.

GUIDE TO AUTHORS

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
 - Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
 - Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
 - 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.
- Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusion in terms intelligible to as wide a readership as possible.
- Manuscripts** may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should be identified in the margin on their first appearance. Equations should occupy single lines if possible: exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on halftones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

New from Nuclepore

Ultrafiltration membranes

Circle No. 19 on Reader Enquiry Card.

- Lowest adsorption losses
- Highest chemical resistance, with autoclavability
- Widest range of molecular weight cut-offs (50-1,000,000)
- High flow rates

Nuclepore, the membrane innovation company of the 80's, has introduced three new ultrafiltration membranes for molecular separations that offer new levels of precision to research, laboratory, medical, and industrial processes.

These new membranes add up to a significant advance in ultrafiltration technology that complements our precision microfiltration products.

For complete details, call or write for our new technical brochure, "Molecular Separations with Ultrafiltration."

Contents continued overleaf

Definitive, Complete, Authoritative

NATURE announces the publication in 1981 of the Annual Directory of Biologicals and Disposable Chemicals. The directory will be available for distribution to all NATURE subscribers in the Autumn of 1981. It will also be marketed separately, offering an even larger distribution.

A New Buyers guide

The basic thrust of the directory will be to provide NATURE subscribers with a definitive reference catalogue from which they may purchase the chemicals and disposables listed.

From research conducted around the world the NATURE marketing staff has determined the need for a directory of biologicals, disposable chemicals and gases. Probably more than any other scientist, the NATURE reader represents the largest potential market for the sale of these chemicals.

Every attempt will be

made to produce a catalogue that will reference the worldwide market of chemical manufacturers, distributors, suppliers, and exporters.

No instrumentation or apparatus listings will be included in this directory; its sole purpose is to provide detailed information for our readers as to where they may secure the biologicals, chemicals and gases for use in their laboratories.

The directory will be cross-referenced and include chemical classifications, product classifications, geographical location of suppliers and other referenced information as needed.

NATURE Directory of Biologicals

What's in It?

The directory will include (but not be limited to) these biological research chemicals

- immunochemicals
 - cell lines
- fine chemicals
 - reagents
 - enzymes
 - isotopes
- monoclonals
- gases, etc.

Companies write for details NOW!

I'm interested in knowing more about Nature's new Directory of Biologicals.

☐ Send me a questionnaire so that my company can have its products listed in the Directory

GUIDE TO AUTHORS

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
 - Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
 - Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
 - 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.
- Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusion in terms intelligible to as wide a readership as possible.
- Manuscripts** may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should be identified in the margin on their first appearance. Equations should occupy single lines if possible: $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on halftones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**, 1 (1975) and **264**, v, 11 Nov. (1976).

ANNOUNCING A MAJOR NEW SERIES FROM MACMILLAN PUBLISHERS

TOPICS IN MOLECULAR & STRUCTURAL BIOLOGY

General Editors:

WATSON FULLER,

Department of Physics, University of Keele.

STEPHEN NEIDLE,

Department of Biophysics, King's College, London.

TOPICS IN MOLECULAR AND STRUCTURAL BIOLOGY is a major new series which is aimed at emphasising interest in three-dimensional structure – the feature which most obviously characterises molecular biology as a discipline.

Each volume will focus on a particular family of biological macromolecules or a well-defined area of structural interest. The contributions will be chosen to reflect the wide range of physical and chemical techniques which characterise contemporary approaches to problems in molecular biology.

The aim will be to highlight topics of high current interest rather than to provide a text with uniform and comprehensive treatment of the field.

The contribution that this series will make in encouraging interest in three-dimensional structure will be clearly derived from a broad experimental base. Descriptions of more speculative model building and conformational analysis will certainly not be excluded but there will be a major emphasis on identifying the assumptions which limit their significance.

The need to place such studies in some perspective would seem to be particularly timely since the rapidly increasing availability within many laboratories of high speed computers with good quality graphics can be expected to stimulate a great deal of work in this area.

The general level of treatment in this series is aimed at research workers in molecular biology and related fields. The major emphasis is on the results which have been obtained and the significance which can be attached to them, rather than on details of the techniques which have been used. This is an approach which should make these volumes of particular value to workers in cognate areas of applied biology and medicine.

VOLUME 1: TOPICS IN NUCLEIC ACID STRUCTURE –

Edited by STEPHEN NEIDLE

Spring 1981; £20; c230pp; ISBN 0 333 26678 1

This work systematically details the most recent data on all structural aspects of oligonucleotides, transfer RNAs, polymeric nucleic acids and chromatin.

Each category is described both in terms of X-ray crystallographic and solution NMR data. A standardised and rational system of nomenclature is used throughout the book.

VOLUME 2: FURTHER TOPICS IN NUCLEIC ACID STRUCTURE –

Winter 1981 c£24 ISBN 0 333 31555 3

VOLUME 3: MOLECULAR ASPECTS OF ANTICANCER DRUG ACTION –

Winter 1981 c£24. ISBN 0 333 31556 1

Send your orders, requests for further information etc. to: Frances Roach, Product Manager, Scientific & Medical Division, Macmillan Publishers Ltd, Houndmills, Basingstoke, Hampshire RG21 2XS, U.K.

GUIDE TO AUTHORS

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*. Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusion in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should be identified in the margin on their first appearance. Equations should occupy single lines if possible: $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

- only one reference number need be used if the reference is to several papers by identical authors.
- first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on halftones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

TM = Trade Mark

- electroneutral, hydrophilic matrix with electroneutral, covalent binding mechanism
- high binding capacity due to high epoxide group content
- macroporous structure with a low water uptake
- high mechanical stability for large-scale industrial processes. Excellent flow properties and good filtration and centrifugation characteristics
- high chemical stability of the matrix and of the bonded ligands
- water uptake independent of pH and ionic strength (from pH 0-14)
- capability of reacting with low-molecular weight ligands in water or in organic solvents

Eupergit - your real choice!

INBRED STRAINS IN BIOMEDICAL RESEARCH

MICHAEL F. W. FESTING

Geneticist at the Medical Research Council's
Laboratory Animals Centre, Carshalton.

£25; 495pp; ISBN 0 333 23809 5

"This is an important work that should be on the shelves of every laboratory carrying out research with vertebrates." *Laboratory Animals*, January 1980.

Inbred strains of mice, rats and guinea pigs have been available for well over half a century and they have made a substantial contribution to many areas of biomedical research.

In spite of these major contributions, particularly in cancer research, there are still many areas of biomedical research in which inbred strains are hardly used at all, and even when they are used their properties are not fully understood. This is the first book to be devoted exclusively to inbred strains and their properties - over 400 are listed with details of their origin and known characteristics. This book will fill an important gap in laboratory animal literature and it is hoped that it will stimulate research workers in areas such as toxicology, biochemistry, parasitology and others, to consider ways in which inbred strains could improve the quality of their research.

Even better together.

Individually, LKB chromatography instruments provide outstanding reliability and consistently accurate results.

But together, they form total, integrated systems that are unequalled in their ease of use and dependability. The LKB 2111 MultiRac® Fraction Collector is the core of just such a system.

LKB excellence in design

The LKB 2111-MultiRac® system combines the ultra-reliable 2111 Fraction Collector with the new MicroPerpex® peristaltic pump, 2210 dual channel recorder and high sensitivity 2138 Uvicord®S UV monitor in one compact package. This entire system takes up less than 2 square feet of bench or cold room space. Yet, every instrument is easy to reach and adjust.

Integrated ease of operation

With the programmable 2111 MultiRac controlling the run, you're assured of accurate, no waste, no problem collections. And with precise pump control of fraction volumes,

automatic flow stop function during tube changes and continuous display of flow rate on the MicroPerpex pump, the system needs minimal interaction time with laboratory personnel.

Versatile and reliable

This new LKB collector draws on years of design experience and incorporates the most advanced circuitry. Because

the MultiRac precisely shifts the drop head, it can accommodate a large variety of collection vessels.

The sophisticated microprocessor controller of the collector lets you select time, drop or precise volume modes, diverts void volumes to waste and can be programmed to save tubes by collecting valleys in large volumes, peaks in small.

See it all together

Ask your LKB representative for more information on LKB complete chromatography systems. See how they work even better together.

GUIDE TO AUTHORS

• Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

• Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

• Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

• 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusion in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should be identified in the margin on their first appearance. Equations should occupy single lines if possible: $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on halftones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

^{32}P nucleotides you simply open and use

Our $> 600\text{Ci}/\text{mmol}$ dNTPs, $[\alpha - ^{32}\text{P}]$ - are now also available concentrated to $\sim 10\text{mCi}/\text{ml}$ in an aqueous solution, ready to pipet directly into your reaction mixture. No need to remove or concentrate the packaging solution. No unnecessary handling.

What's more, we've extended their radiochemical stability significantly with 10mM Tricine, a buffer known to be compatible in research systems. Biological testing by nick translation verifies their biological activity and assures you of reliable performance.

NEG-012A dATP, $[\alpha - ^{32}\text{P}]$ - NEG-014A dGTP, $[\alpha - ^{32}\text{P}]$ -
NEG-013A dCTP, $[\alpha - ^{32}\text{P}]$ - NEG-005A dTTP, $[\alpha - ^{32}\text{P}]$ -
 $> 600\text{Ci}/\text{mmol}$, $\sim 10\text{mCi}/\text{ml}$, in 10mM aqueous Tricine buffer solution (pH 7.6), Combi-V-Vial

Produced weekly and shipped daily. Send for complete ordering information on these and our standard concentration dNTPs, $[\alpha - ^{32}\text{P}]$ - .

Not for use in humans or clinical diagnosis

Ribonucleoside 5'-[α - ^{32} P] triphosphates

Straight from the bottle every week!

From 7th May 1981

Fresh batches of all 4 [α - ^{32} P]NTP's at >400Ci/mmol available every week.

Two formulations

- 10mCi/ml in aqueous solution containing 5mM 2-mercaptoethanol
- 1 mCi/ml in 50% aqueous solution

Radiochemical Purity

- All batches analysed by HPLC

Aqueous solutions at 10mCi/ml

- Supplied in "Duoseal V-vials"
- Reduced need for evaporation of the solvent
- Avoids the risk of decomposition during evaporation
- Reduced handling minimizes risk of wastage, spillage and contamination

Please ensure you have your copy of our despatch schedule

Minerals and Rocks

Editors in Chief P J Wyllie

Editors A. El Goresy, W von Engelhardt, T Hahn

This series of monographs represents the continuation of 'Mineralogie und Petrographie in Einzeldarstellungen' on an international level. It presents up-to-date reviews and reports of carefully selected topics in mineralogy, geochemistry, petrology and isotope geology, including applications to industrial processes and products. Designed to supplement existing textbooks, many of these volumes can be used as the basis for advanced seminars.

A step towards the solution of the andesite problem

Volume 16 J. Gill

Orogenic Andesites and Plate Tectonics

1981 109 figures, 21 tables Approx 420 pages
Cloth DM 98,-, approx US \$ 46 70
ISBN 3-540-10666-9

The solution to the question of andesite genesis is a major, multidisciplinary undertaking facing geoscientists in the 1980's. **Orogenic Andesites and Plate Tectonics** was written in response to the growing need of researchers in this area for a clarification of the long-standing problem and identification of profitable areas for future investigations.

This book critically summarizes the vast relevant literature on the tectonics, geophysics, volcanology, geology, geochemistry, and mineralogy of andesites and their volcanoes. The author cites over 1100 references in these specialties and includes information on the location and rock composition of more than 300 recently active volcanoes. In addition, he provides a systematic and original evaluation of genetic hypotheses.

Numerous cross-references enhance the integrated subject development which consistently emphasizes the implications of data for theories of magma genesis. **Orogenic Andesites and Plate Tectonics** will prove an invaluable reference source to researchers and graduate students in the geosciences seeking a careful evaluation of genetic hypotheses and key data, arguments or gaps in this promising field.

GUIDE TO AUTHORS

• Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted, it is advisable to consult us before writing a review article.

• Articles may be up to 3,000 words long with at most six displayed items (figures and tables), they are reports of major research developments.

• Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words, they have at most three or four displayed items.

• 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusion in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should be identified in the margin on their first appearance. Equations should occupy single lines if possible. $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

- (i) only one reference number need be used if the reference is to several papers by identical authors
 - (ii) first and last pages of references should be cited
- Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material ideally, an unlettered original and three lettered copies should be provided, labelling on halftones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov (1976).

You need today's LANCET more than ever before. Here are a few reasons why.

1. THE LANCET is both timely and topical.

When an author submits an original article to THE LANCET, it is published with dispatch—usually in 4 to 8 weeks. After the issue is rushed to more than 50,000 subscribers around the world, comments and responses pour in from readers who speak their minds, knowing their views will get international attention. In 2 or 3 weeks their rebuttals, remarks, and reminders appear in the 30 to 40 columns of Letters to the Editor that are a regular feature of each LANCET. These letters keep you up to date on your colleagues' thoughts and actions, and give a distinctive personality to the journal.

THE LANCET

Pope John Paul II in Hiroshima

The Pope's visit last week to non-Christian Japan showed how well this indefatigable traveller can tune his speeches to his audience. With the faithful thin on the ground, general issues took precedence over those that domestically occupy his Church. The result was a more open discussion of some perplexing problems than in the Philippines the week before. And nobody should complain that the Pope followed other statesmen to Hiroshima for a major speech on the problem of nuclear war. The melodrama of the site ensures that some notice will be taken of what is said. Not surprisingly, the Pope's discussion was a good deal more perceptive than many that have preceded it. The visit also provided him with an opportunity to pat on the back one of the two sponsors of the occasion, the United Nations University. The university's new rector, the Indonesian Soedjatmoko, seems well placed to help the university make a mark in its chosen field of interest, the development of developing countries.

The danger facing those who make speeches at Hiroshima is that of following the same hackneyed theme. Nuclear weapons are awful things, and the product of scientific research, from which it follows that the sharpest dilemma is the Promethean dilemma. The Pope fortunately had the wit to acknowledge that this task has political as well as ethical or moral dimensions. However powerful may be people's collective wish that nuclear war should not break out, their political differences ensure that the danger will remain alive. It would be asking too much to accept the argument, for which there is some justification, that only the balance of terror has kept the peace these past thirty years. But the implication of his remarks (at Nagasaki) that the United Nations must more powerfully assume a peacekeeping role is needlessly unearthly, the United Nations is a place where governments with different interests meet, as often to declare their differences as to resolve them. Although the United Nations has from time to time passed high-sounding resolutions on the need for "general and complete disarmament" (known as "GCD" in the trade) the painfully slow processes of the Committee on Disarmament shows what problems lie ahead.

Fortunately, not all problems are such inherently gloomy problems. Although the theme of the Pope's speech last week was "the ethical problems of the technological society", he reminded those who heard him that "we all greatly benefit" from the application of science and technology. In the past few gloomy years, optimism on this score seems to have melted surreptitiously away, not so much from anxiety about war as because of the faltering of the industrial economies and the predictable but nonetheless bitter failure of efforts such as the United Nations conference on technology and development two years ago. But can it be that the promise of science and technology for the improvement of the human condition, widely believed only a few years ago, has evaporated overnight? Is it not more likely that people have become discouraged? And, in these circumstances, may it not be especially valuable that vaguely incongruous figures like the Pope should go about reminding people that the promise is still there to be captured?

But how? At Hiroshima, the Pope said that the need was for a "moral about-face". Translated into the language of everyday politics, the implication is that governments must become more serious in their consideration of documents such as the report of the Brandt Commission on the problems of contemporary development, more imaginative in their management of domestic wealth and liberty and more courageous in their handling of dealings with each other. But, in the last resort, governments —

even illiberal governments — are merely the products of their people. Is the practical message of what the Pope was saying last week about the moral responsibility of the scientific community that the time has come when governments should be reminded again, as they have been *ad nauseam* in earlier decades since the Second World War, that the time has come to start solving problems, not to be mesmerized by them?

Ructions in space

The European Space Agency is using unaccustomed undiplomatic language in its attempts to persuade the new United States Administration not to force the cancellation of the joint venture to put a pair of spacecraft into polar orbits about the Sun. Rumours that this might be one of the consequences of the cut in the budget of the National Aeronautics and Space Administration have been circulating in Washington for several days (see *Nature* 26 February, p 738). The European reaction to the news that the rumours are true has been understandably tetchy. Europe, the European Space Agency is saying, has been led up the garden path, has been induced to lavish a substantial part of the meagre funds available for planetary exploration on a project whose value will now be much reduced (see page 3), and which may even have to be abandoned altogether. By asking that member states should send their diplomats into action in Washington, the European Space Agency has broken new ground in the foreign relations of multilateral agencies like itself. The bad temper in its public statement on the problem suggests that good relations may be at an end.

Luckily, that time may not yet have arrived. There remains a chance that the American half of the solar polar mission will be restored in the budget to be published on 10 March. More to the point, there is every chance that the United States Congress, still not quite certain what to make of President Reagan and his well-intentioned but draconian fiscal policies, will write back into the budget some of the items the President is planning to strike out. (And then, of course, it is always possible that the White House might decide not to spend the money, anyway.) In short, it is too soon to be supposing that the solar polar experiment is a washout. What has happened is more subtle but also more important.

Domestically, the United States space programme is in a mess. For the past three years, the space shuttle, the machine intended as the launching vehicle both for commercial and scientific spacecraft, has been in trouble. It is already two years late, and further difficulties may come to light in the critical months ahead. Yet it is too late to complain that the United States should have embarked on a quite different programme of development ten years ago, when the Apollo programme ended. Willynilly, the shuttle is the only sufficiently versatile launching system in sight. If its use is further delayed, the consequences will be more serious than the cancellation of the American half of the solar polar project. The European half may be without a launcher as well, while a whole string of communications satellites will have to find their way into synchronous orbits by quite different means. Worse still, for the scientific community, the Large Space Telescope in which the European Space Agency also has a substantial stake and which the United States Administration has so far (to its credit) kept free from cuts, will also be in jeopardy. Bad temper is, in the circumstances, inappropriate.

Looking further ahead, however, the European Space Agency

is right to be alarmed. In the past few years, it has dawned on European governments that they must have access to some way of launching spacecraft of all kinds. The chance to join the shuttle project as a partner has however gone. The European launcher Ariane may have a future, if only as an insurance policy against further delay of the shuttle and as an assurance of independence, but is not the ideal way of meeting the need. The space agency itself, now under new management, has a poor public reputation stemming at least in part from its bureaucratic ways and from the way in which member governments appear to regard it as their first objective to ensure that their contributions are required by contracts placed with national companies. Many scientists concerned to put scientific experiments into space have found it easier to work with the American agency than with that in Paris. The first lesson to be learned in Paris from the threatened cancellation of the American half of the solar polar project is that it should put its own house in order. Only then will it be able to take the lead in making sure that European governments collectively have a view of their future role in this important field.

The European Space Agency would at the same time do well to draw a wider lesson from what is going on in Washington. The space budget is being cut not only because of the technical problems with the shuttle but also because expenditure of this kind is not immediately productive. In the long run, it is better for Europe that the American economy should be healthy (free from inflation) and productive than that funds should be found for the second half of the solar polar project. And, it would be folly if the growing European enthusiasm for space projects were further to undermine the economic health of Western Europe.

Questions answered

The British predilection for studying the machinery for administering publicly supported science has burst out again, this time in the House of Lords (*Nature* 26 February, p 741). British governments seem constitutionally unable to decide for themselves what sensible steps to take, and usually set up *ad hoc* committees to tell them what to do. The select committee of the House of Lords is an unexpected but a better way of tackling the problem. The committee has also taken the unusual step of inviting written evidence from anybody, and the specific questions it has asked show that its inquiry may well be radical. What follows may help to start the ball rolling.

The most important, because the most novel, group of questions is that labelled machinery of science. Could the relationship between the British government and the scientific community be improved and, if so, how? The obvious difficulty is that, formally, there is no such thing as a scientific community. There are a few organizations, the Royal Society chief among them, which are sufficiently diverse to be consulted as if they were representative, and so eminent that the advice they give is rarely foolish. However radically the House of Lords committee tackles its inquiry, these influences on government will (and should) continue. Moreover, it would be fruitless to engage an army of constitutional lawyers to devise some way in which the wider scientific community could speak with even greater representative authority. The truth is that opinions within the scientific community differ about all the questions the committee has asked as well as about more specific problems.

What the British government needs is some means by which it can sense the diversity of scientific opinion on contentious issues, forming in the process a judgement about which views should be taken seriously, and at the same time making more effective use of the imagination and willingness to help of people working in laboratories of all kinds. The mechanism required is more like a lightning-rod than a forum. Whether it should be more like the United States President's Science Advisory Committee than the British Advisory Council on Scientific Policy of the 1950s is less important than that it should be accessible to all who want to tell it something.

Given such a device for drawing attention to important problems, some of the select committee's questions would be

answered. Thus, while no amount of organization can ensure that there is sufficient communication between those responsible for the administration of science in industry, research councils and government, common experience shows that public servants respond diligently to well-considered public complaint or even to constructive suggestion. To be effective over the whole field the select committee has mapped out, a committee of this kind would have to be adequately serviced — previous essays in this direction have been less than successful because they have been run on a shoestring. The terms of reference of the existing Advisory Council on Applied Research and Development are too narrow to do what is now required, and the council seems shy of tackling questions of how well government machinery is working. It is, however, essential that any such organization should be independent of particular government departments. The Council for Scientific Policy of the 1960s, which did some useful work, was too dependent on the Department of Education and Science to be effective. The need now is for a channel for communication free from departmental interests. The House of Lords is well placed to decide how such a committee should be plugged into the government machine. Direct responsibility to the Prime Minister would be the constitutional ideal but would make a mountain out of a molehill. A connection with the Treasury would not offend the lawyers and could be fun. Otherwise, the best choice would be a return to the 1960s, when the Lord President of the Council was responsible for the Council on Scientific Policy.

Other questions on the list from the House of Lords bear on the issue of the Rothschild customer-contractor principle. In spite of the mixed experience of the past decade, it would be wrong now to give up the notion that government departments should be equipped to decide scientific questions relevant to their own work, and to commission their own research. But the system in which departments were required to appoint chief scientists to manage their scientific affairs has not always worked well. Some of those appointed have not been up to the job, few of them have been in their posts long enough to learn what to do and none of them has been paid enough. However, there can be no general rule for deciding how much money should be spent by departments and how much by research councils. Research councils should have enough money to discharge their responsibilities properly, and government departments should spend money on research in the expectation of winning tangible benefit as a result. Some of the imperfections of the present system, and especially the difficulties which have arisen in the financing of applied research in which no government has a commanding interest, would not exist if the arrangements for dividing the science budget between those dependent on it took more account of the scientific merits of their different programmes.

These are the easy questions. The committee's question about the adequacy of the government's own scientific manpower is much more difficult. What should be done about the scientific civil service? And what should be done to equip the British civil service as a whole to grapple with modern problems? The British government is at present too directly involved in research in its own establishments (shockingly so in defence research). If the committee does more than skate round the manpower problem, it will recommend that the government reduce its own research effort drastically (but provide better careers for those who remain) and also tackle seriously the recruitment of scientists in mid-career to the civil service proper. The present system merely perpetuates amateurism and ensures inexpert advice.

The hardest question of all, however, is missing from the list circulated by the House of Lords. What is to be done about defence research? Only two weeks ago (*Nature* 19 February), the European Commission was pointing out that defence research is a larger proportion of all research in the United Kingdom than elsewhere in the European Community. Outsiders have no means of telling how necessary this vast enterprise may be, although there is every reason to believe that the huge defence laboratories could be used more effectively to foster industrial change without hazarding national defence. The select committee should think of adding this topic to its agenda.

Open row about joint space project

European space agency plans protest

Washington

Western European nations have agreed to organize a top-level protest to the US State Department at the proposal of the National Aeronautics and Space Administration (NASA) to withdraw its spacecraft from the International Solar Polar Mission.

The mission, under which two spacecraft would be flown simultaneously over opposite poles of the Sun, is being organized jointly by NASA and the European Space Agency. Originally each agency was to have supplied one of the spacecraft, the two being launched from the space shuttle in 1985. NASA has now decided to absorb some of the massive cuts in its space science programme required by the Reagan Administration by terminating the work on its own spacecraft. It would still provide support facilities for the European spacecraft if the European Space Agency decided to press on alone.

The European agency issued a strongly-worded statement last week saying that it considered NASA's actions to be a unilateral infringement of the memorandum of understanding signed between the two countries, and warning that it could have severe consequences for future co-operation in space research between Europe and the United States. Now several countries, including France, West Germany, Italy and the United Kingdom, have agreed to make a joint protest to the State Department, hoping that NASA can be persuaded to change its mind. Without the participation of the US spacecraft, which would have provided the first opportunity to study a star at close hand, the value of the mission will be severely limited.

Within NASA, however, officials have little hope that the proposed cuts will be reversed, since next to the space shuttle programme NASA's top priority has been to keep intact its two main space science projects, the space telescope and the Galileo mission to Jupiter.

NASA officials have stressed the importance they attach to maintaining links with European colleagues, as both acting deputy director Anthony Calio and the director of the Goddard Space Flight Center, Dr A. Thomas Young, pointed out when Mrs Margaret Thatcher visited the centre during her visit to Washington last week.

However, NASA has had to take some hard decisions itself, and apparently decided that the cancellation of its share in the solar mission was the least of several evils. On the other hand, the deferral of the

gamma-ray observatory and of the Venus Orbiting Imaging Radar have been demanded by the White House.

NASA has now been asked by the Office of Management and Budget (OMB) to make even more cuts in its next year's budget, following the discovery that the size of the required federal budget cut had been underestimated. Although it is not known where these most recent cuts will fall, one rumour is that funding for astrophysics experiments on the second Spacelab will be withdrawn, a decision which would particularly hit British scientists.

When rumours began to circulate in Washington last month that OMB was proposing to scrap Galileo, West Germany — which is developing several of the instruments to be flown on both the orbiter and the probe and is contributing about \$50 million to the cost of the mission — protested strongly to Secretary of State Alexander Haig. Mr Haig's subsequent intervention with OMB is said to have contributed significantly to the decision not to terminate the project.

No mention was made at that time of a possible threat to the solar polar mission. NASA was given its total required budget cut but left to decide where the cuts would fall. Cancelling the solar polar mission spacecraft would save between \$250 and \$300 million total costs over the next eight or nine years.

Gloom at prospect of cancellation

Officials at the European Space Agency (ESA) are too upset by the decision by the National Aeronautics and Space Administration (NASA) to ditch its solar-polar spacecraft to talk about contingency plans, preferring to await the results of diplomatic efforts to get the decision reversed before 10 March when the federal budget goes to Congress and after which changes cannot be made. Nevertheless it is almost certain that, if it has to, ESA will go it alone, having already invested too much in the mission to abandon it.

The European Space Agency council meets this Thursday (5 March) to decide on its reaction to the US moves. There is still a chance that some of the US instrumentation could be transferred to the European craft, although European experiments on the US craft would be given higher priority. The agency could equally well decide that, without full US participation, the mission is not worth pursuing, a decision which would severely disrupt its space science budget.

NASA's final proposals are expected to be announced next week, when Mr Reagan gives Congress a detailed list of his proposed budget reductions. There will undoubtedly be some opposition in Congress if the mission remains among the proposed cuts. Senator Jack Schmitt, an ex-astronaut and now chairman of the science and space subcommittee of the Senate Commerce Committee, said last week that he was very concerned that the decision could jeopardize future cooperation, particularly at a time when Europe seemed to be moving ahead of the United States in some areas of space technology.

But, as a loyal supporter of Mr Reagan, Mr Schmitt said he also acknowledged that there was a need to make substantial cuts in federal spending to restimulate the economy — and that space science, together with other research areas, would have to accept its fair share. **David Dickson**

The International Solar Polar Mission was originally conceived as a two-spacecraft mission that would observe dynamic and variable phenomena at high solar latitudes. The spacecraft's journey round Jupiter would also provide the first opportunity for spatially and temporally resolved measurements of Jupiter's magnetosphere. Some of the experiments to be flown on the two spacecraft would be identical but others would complement each other.

A decision to abandon the NASA spacecraft would mean that spatial and temporal resolution could be achieved less adequately only by comparison with simultaneous observations from the Earth. In all probability, it would also mean that the NASA spacecraft's ability to make optical measurements of the Sun's surface — unlike the ESA spacecraft, it has a pointing device — would be lost.

Each spacecraft is to house some of the other partner's experiments. It is thought unlikely, because of commitments already made, that the experiments to be flown on the ESA spacecraft could be changed at this late stage. Fortunately NASA has said that it will continue support of its experiments to be flown on ESA's craft. That, however, begs questions of the

future of European experiments for the NASA vehicle. According to ESA, work on those experiments is already well advanced and substantial sums of money, which will have been spent in vain if NASA's decision stands, have already been committed. The total cost to completion of the two spacecraft is an estimated \$140 million, \$100 million of which is already accounted for.

Judy Redfearn

European fusion

JET's ambition

JET, the joint European tokamak nuclear fusion experiment, may cost another 400 million European units of account (EUA) (£216 million) if first the JET Council — which oversees the project — and then the European Commission agree. The money would be spent over five years, beginning in 1982, and would extend JET to its full design performance, including bulk ignition of a deuterium-tritium plasma. "If they want the results, they'll have to pay" said Dr Hans-Otto Wüster, director of JET, of the European governments last week.

The original cost of basic JET was 185 million EUA at January 1977 prices. Inflation in Britain, coupled with the strength of the pound sterling and a serious underestimate of the cost of diagnostic equipment, has pushed that basic price to something nearer 300 million EUA, but even so the proposed extension would more than double the total cost. Dr Wüster, however, points out that the extra cost is only twice the annual budget of the CERN laboratory in Geneva.

The rush to extend JET is occasioned by two factors. First, machines like JET seem to have a better chance of reaching ignition, the nuclear burning of the plasma, than when they were designed in the early 1970s. Second, the European Council of Ministers has asked for a proposal for fusion research in Europe for the next five-year period, 1982–86, by 1 July this year.

Competition with the United States is also in mind. Princeton's Tokamak Fusion Test Reactor is due to begin experiments in 1982, and the somewhat larger JET in early

1983. Princeton is being pushed hard by the US Department of Energy to try ignition early. If all went well, JET's initial non-nuclear plasma experiments would then look pretty tame. On the other hand, if either laboratory is too hasty in introducing radioactive tritium, repeating early experiments will be very difficult, requiring remote handling and radiation protection.

Important plasma physics problems remain to be solved. Present optimism arises because two predicted limits on plasma containment have not been observed in existing small tokamaks. "Trapped particle instabilities" were expected to set in at temperatures above 30 million K, but the smaller Princeton tokamak has reached 70 million K without seeing them. And the ratio of plasma pressure to magnetic pressure was thought to be limited to about 1 per cent, but values of 8–9 per cent have been reached. While experimentally encouraging, these results are theoretically puzzling, so the JET and Tokamak Fusion Test Reactor regions may still hold surprises.

Dr Wüster is therefore cautious, offering 3–4 years of plasma at JET before attempting ignition around 1987. But the bulk of the spending on "extended performance" would have to be undertaken in 1982–86. In January, the JET Council gave Wüster a 400 million EUA guideline for the extended performance, and asked him to say what he could do with that. If, this month, his proposals are adopted, it will be for the European Commission to consider whether to include it as part of the 1982–86 research programme.

Conflicts between the interests of the national laboratories and money-hungry JET seem likely to be resolved at JET Council level, but the commission must also test the interest of governments, for which reason it has set up a new committee — the Consultative Committee for Fusion Programmes — which will be dominated by the representatives of government departments from whose coffers the money must ultimately be found.

The commission has also established an expert panel, the European Fusion Review Panel, to make recommendations for a long-term programme, beyond the present generation of machines. This panel will also report to the commission before July, in time to influence the final commission proposal.

One question to be dealt with is whether Europe is wise to commit itself so heavily to one design of fusion device, the tokamak. In the United States, there is also substantial work on the potentially simpler magnetic mirror confinement and inertial confinement. Wüster says that it makes sense to push ahead with the device that will most quickly yield ignition, so as to win practical experience of the problems of operating fusion reactors of all types. We shall see whether the European Fusion Review Panel agrees with him.

Robert Walgate

United States budget

More cuts

Washington

True to its political convictions, when full details of its proposed budget cuts are announced next week, the Reagan Administration is expected to eliminate virtually all the federally sponsored programmes initiated by President Carter to stimulate innovation in private industry.

President Carter's initiatives were the result of a broad-ranging, eighteen-month study largely instigated by the Office of Science and Technology Policy. Recommendations were made by eight independent advisory committees, and submitted to the White House with proposals from individual federal agencies.

From these, a package of 32 proposals was eventually accepted and announced by Mr Carter in November 1979. Although criticized at the time for not going far enough, it was generally agreed that the proposals made up a modest set of experimental and exploratory approaches aimed at bringing industry, government and the universities closer together.

The interventionist approach which the new programmes embodied, however, has found little sympathy with the new Administration, which sees its principal strategy for stimulating innovation as improving the financial incentives for investment, not direct federal participation.

The Administration will therefore be expected to drop support for any future co-operative generic technology centres, even though specific legislation setting up these centres was approved by Congress last year, and \$5 million allocated to their support (*Nature* 286, 195, 1980). From the three centres initially proposed, only one, in Detroit, is likely to survive as plans were agreed before the election, although even this is uncertain since it will depend on the centre's ability to raise matching funds from industry.

Other projects previously under development in the Commerce Department and now expected to be phased out include proposals to establish state-based Corporations for Innovation Development to help entrepreneurs gain access to investment capital, and the new Office of Technology Strategy and Evaluation.

It is also rumoured that the new Administration may not seek a successor to Dr Baruch, who as Assistant Secretary for Productivity Technology and Innovation was responsible for science and technology programmes within the department. This would be opposed by Congress, which spent much time last year discussing the Carter Administration's initiatives, and supported their general thrust.

Another of Mr Carter's initiatives which will be overruled is the Co-operative Automotive Research Project (CARP), originally proposed by Transportation Secretary Mr Brock Adams as a means of

JET upgraded

The extension of JET to full design performance would involve increased magnetic confinement fields, additional heating of the plasma, facilities for storing and handling tritium, and remote handling equipment for experiments. Specifically, the peak toroidal field coil power would be increased from 250 MW to 380 MW, total magnetic field at plasma centre 27.7 kG to 34.5 kG, plasma current from 3.8 MA to 4.8 MA, and additional heating power from 4–10 MW to 25 MW.

Robert Walgate

generating joint government and industry support for long-term research, and already approved by Congress with a budget of \$12 million for the first year. In his budget proposals of two weeks ago, Mr Reagan said that "federal financing of long-term research to benefit a particular industry is an inappropriate allocation of federal funds." He is proposing to rescind the full amount appropriated by Congress for the current year, and to terminate the whole programme.

At the National Science Foundation, schemes for encouraging greater technological innovation in small businesses, and for forging closer links between industry and universities, will remain in force, but will not get the substantial increase in funding that the Carter Administration had promised as part of its innovation package.

Support for small industries innovation, for example, was to have been almost doubled, from \$7.5 million to \$14.5 million next year, following its earlier success, but will now be cut back. So too will increased funds for engineering education, but the proposed 20 per cent increase for engineering research is likely to remain.

In contrast with the cuts being proposed in measures which would increase federal involvement in the innovation process, other steps initiated by Mr Carter to reduce the federal role have been warmly endorsed and built upon by the new Administration.

Efforts to reduce the burden of health, safety and environmental regulations, for example, have already been expanded. As expected, Mr Reagan has proposed, along with his budget reductions, a set of regulatory reforms which would submit all new and existing regulation to strict cost-benefit analysis.

Similarly, additional patent reform legislation has already been introduced into the new session of Congress which would expand on Mr Carter's patent reform bill giving universities and small businesses patent rights on federally funded research.

David Dickson

UK research councils Allen accused

The UK Science Research Council is being hauled over the coals for sloppy bookkeeping. Its chairman, Sir Geoffrey Allen, is to appear before the Public Accounts Committee of the House of Commons on 17 March to explain irregularities in the council's funding in the financial year 1979-80. Details are hard to obtain because the council, usually frank, is saying nothing for fear of offending parliamentary privilege.

Part of the problem stems from the cash bonus that Mrs Shirley Williams, then Secretary of State for Education and Science, obtained for the research councils in 1978. The council's share was £33 million over the four financial years

1979-83. A circular was thereupon sent around universities asking for applications to the council to replace worn-out equipment. Truck-loads of applications followed, worth £37 million, of which the council awarded £7.5 million. In the event, a change of government followed, funds were cut and the council received only £5 million.

Another question mark hangs over the university grants current in March 1980, which represented an increase in value of £31 million (34 per cent) over the previous year. There appears to be no indication that this large increase was planned. The exact amount of overspending remains unclear, but much of the money was spent by the Science Board (responsible for such topics as physics of solids and liquids, chemistry and biology). The new Spallation Neutron Source at the Rutherford-Appleton Laboratory at Chilton seems to have been a principal beneficiary.

Other misdemeanours are procedurally more serious. The Auditor General, Sir Douglas Henley, has already complained that the postponement of certain payments into the 1980-81 financial year, as part of an attempt to alleviate the financial deficit, contravenes government regulations. The Public Accounts Committee will also, no doubt, be asking about the council's calculation that the capital value of a site near Slough, yet to be vacated, could be regarded as a part of the income for 1979-80.

The council appears to have been the victim of government financial vagaries combined with inflexible accounting procedures. But the extent to which the problems are also self-generated will not be clear until 17 March.

Sir Geoffrey Allen, formerly the council's accounting officer, came to the end of his spell as chairman in October. The name of his successor is expected to be announced within a few weeks.

Philip Campbell

Soviet research

More home growth

The new Soviet Five-Year Plan calls for all branches of the economy to be brought up to the "most up-to-date levels of science and technology." Just how to do this is clearly causing the Soviet leadership considerable anxiety. At the Twenty-Sixth Congress of the Communist Party of the Soviet Union last week, Mr Brezhnev called on the whole scientific establishment to reassess the research and development basis of Soviet industry and to propose ways of regrouping the "scientific forces".

Not only the Academy of Sciences and the State Committee for Science and Technology should take part in this audit, said Mr Brezhnev, but also the science-based industries, including defence. Since Soviet military research is organized quite

separately from the civil sector, this last proposal suggests genuine concern, not simply congress window-dressing.

Mr Brezhnev singled out a number of fields of technology where "impermissible sluggishness" had led to delays in implementing "promising developments" — the continuous casting of steel, powder metallurgy, custom-built DC transmission lines and high-strength artificial fibres. Falling behind foreign competitors, he said, leads to massive expenditure of foreign currency for equipment and technology which the Soviet Union could have produced at home. Soviet potential technological self-sufficiency has been a feature of propaganda speeches since the January 1979 United States embargo. Mr Brezhnev's speech, however, referred rather to one of the major concerns of Soviet research policy: why is there often so long a gap between obtaining a new result and implementing it in production?

Mr Brezhnev suggested two possible lines of reorganization, which appear mutually contradictory. On the one hand, he stressed the Central Committee's support for an increased responsibility for the Soviet Academy of Sciences, and argued a "flexible and mobile" organization of research that would not tolerate "fruitless laboratories and institutes", but would respond "attentively" to the needs of scientists for equipment, instruments and pilot plant facilities. Taken in isolation, these remarks suggest more scope for serendipity and the capacity to switch rapidly from one line of research to a more promising alternative.

Mr Brezhnev went on to say, however, that the major sciences (including basic research) should concentrate more on solving "key national economic questions" and "discoveries capable of making genuinely revolutionary changes in production". The formulation of these tasks, he said, is the task of the central planning bodies and the State Committee for Science and Technology. The exact spheres of competence of the Academy and State Committee are frequently difficult to define, and Mr Brezhnev's speech does not make the issue easier. The previous Congress (1976) had made the Academy responsible for coordinating all science throughout the country, and although, to judge from the report to Congress of Dr Anatoli P. Aleksandrov, the Academy's president, much still remains to be done, there is no suggestion that the task should be taken out of the Academy's hands.

Dr Aleksandrov's report, moreover, reviewed a wide range of recent achievements, from particle physics and cosmology to the utilization of Estonian shales and the need to develop coal liquefaction and gasification techniques. Academy scientists, he said, have made notable advances in thermonuclear fusion, and in prolonging the life of agricultural machinery.

Discussion of future plans, at a Congress

of this type, is always to a large extent, orchestrated. A clear example was the intervention of Sharaf Rashidov, Party chief of the Uzbek SSR. Mr Brezhnev had called for a new food production programme. Mr Rashidov suggested that a "tremendous contribution" could be made by diverting the northern rivers to the Volga Basin and the Siberian rivers to the steppes of Kazakhstan and Central Asia. Plans for such proposals, however, are of course already well under way, and a considerable engineering effort earmarked for them in the new Five-Year Plan.

Dr Aleksandrov, however, had a lightertouch. One of his major proposals began as an apparent piece of by-play with Mr Brezhnev and the Leningrad Party chief Grigori Romanov, about the development of an anti-influenza spray which Mr Brezhnev had requested at the last Congress. (The very fact of such jesting is, in itself, a suggestion that the Academy's auspices are exceptionally favourable at present.) The successes which Dr Aleksandrov reported — 10 million doses of the spray produced in 1980, 25 million scheduled for 1981, and the incidence of influenza in Leningrad cut by two-thirds, were simply a build-up. Soviet microbiological production, suggested Dr Aleksandrov, should be reorganized under a special Ministry of the Biotechnical Industry. **Vera Rich**

German nuclear power

Closures and delays

Four German nuclear power stations, representing a third of the country's 10,000 MW of nuclear power, are to close for at least a year for the complete replacement of their primary cooling circuits. The Bonn Nuclear Safety Commission ordered the closures after deliberating for three years over this issue, involving General Electric Company-designed boiling water reactors (BWRs) constructed under licence between 1973 and 1979.

Small leaks and cracks had developed in the primary circuit of these reactors which carry cooling water through the nuclear cores. The cracks appeared to be spreading by stress corrosion (combined effects of mechanical and thermal stress and chemical corrosion). The commission has concluded that uneven quality, poor choice of materials, and a thin gauge of steel for

the pipework were to blame, and that the circuits must be replaced to avoid the danger of a potentially catastrophic cooling failure. The cost of replacement has been estimated at DM 1,200 million (£250 million), with an equal sum for the loss of electricity sales. However, the four responsible utility companies have decided not to close down all the reactors simultaneously. One is already being refitted, and should be on-power again by the summer, and the others will be dealt with in sequence.

The boiling water reactors have not been a success, and Germany is now concentrating on the Westinghouse pressurized water reactor design, originally licensed by Siemens. Siemens and the constructors, AEG, are now merged in the company Kraftwerk-Union, and the excessive cost-trimming which may have led to the BWR problems is not expected again.

Meanwhile, the federal government's nuclear policy continues to be threatened by opposition from the left wing of the Social Democratic Party, particularly in Hamburg where construction of the Broksdorf reactor has been brought to a halt by demonstrations. Over the weekend, 50,000 people demonstrated at Broksdorf, and 127 policemen were injured. According to some observers, many of the demonstrators were not local, but represented national left-Social Democratic, Communist and Green Party groups. Broksdorf thus appears to have become a symbol of left-right conflict in Germany. **Robert Walgate**

Human growth hormone

Pituitary slump

Britain's supply of pituitary glands, from which human growth hormone (HGH) is extracted to treat 600 British children who do not produce it normally, has fallen by at least a third in the past year — to a level too low to keep up with demand. This has happened since responsibility for HGH extraction shifted, in June last year, from two Medical Research Council-funded researchers to the Department of Health and Social Security (DHSS). Bureaucracy has strangled their collection procedure, Dr Philip Lowry, one of the researchers, said last week. The collection rate has now stabilized at around 42,000 glands a year, DHSS claims, accounting for almost all patients who end up in a National Health Service mortuary — but the supply from public mortuaries (where victims of violence and accident are given postmortem examinations) has almost dried up. In the last year of the Medical Research Council scheme, 70,000 pituitaries were collected, said Dr Lowry.

Extraction of the hormone is now done at the Centre for Applied Microbiological Research at Porton Down, which has become increasingly involved in health

service functions since it was transferred to the Public Health Laboratory Service from the Ministry of Defence two years ago. Of two processes, depending on the form in which pituitaries are collected, Porton chose the older, using acetone-dried glands. This yields around 8 clinical units of HGH per gland as opposed to 15 by the newer frozen-gland system (which has been adopted in New Zealand and Canada), but collection is easier: the extracted gland needs only to be popped into a bottle of acetone, instead of a container packed around with dry ice. However, says Dr Lowry, who developed the frozen-gland process, clinical trials over the past year have shown that the HGH produced from frozen glands is the more pure, provoking no immune reactions — unlike acetone-dried HGH, which often contains modified and agglomerated versions of the protein, and can be rejected by the child.

The 336,000 units of HGH made available by the Porton process each year in Britain are enough to supply only 430 of the 600 children with a full dose of 15 units a week. So far, Porton has been relying on an excess of material collected through the old system, but soon the reduced supply of glands must have an effect on the supply of HGH. It may then be necessary to buy HGH from foreign producers, where market pressures have pushed up the price to 50 times the cost of home-produced hormone. Porton is also working on producing HGH from *Escherichia coli*, genetically engineered to excrete the hormone, provided by the Swiss firm Kabi-Vitrum in association with the California-based genetic engineering company, Genentech, but production is not likely to be significant for a year, at least until clinical trials, now under way at Great Ormond Street Children's Hospital on Genentech-produced hormone, are complete. Moreover, the genetically-engineered hormone is slightly modified: it has an extra amino acid (methionine) tacked on one end, and there is a possibility that, like agglomerated HGH, it may provoke an immune response.

Meanwhile, the DHSS is trying desperately to restore supplies of pituitaries from public mortuaries. But the department is facing numerous legal and personal obstacles. Legally the coroner must consent, and the relatives give written permission. But a death involving a public post mortem is usually an unexpected one, relatives are shocked, and the case does not seem so compelling as for a kidney or a heart. The DHSS recently sent 200 letters and made as many telephone calls to coroners and pathologists requesting their urgent cooperation — but the department has little hope that the supply will rise much in consequence.

A few months ago, supply problems were even more desperate, when hospitals too were failing to provide the glands. This may have been because morticians, in March 1980, negotiated a new contract

In addition to the four boiling water reactors (producing 3,300 MW), Germany has another six power reactors producing 6,600 MW. Another nine, to produce around 10,000 MW, are under construction, including the SNR fast breeder research reactor, and a high temperature reactor near Cologne. Construction is halted at two further sites (Broksdorf and Wyhl because of local and political opposition).

under which their wages were increased to cover extra duties — which included the extraction of pituitaries. Previously they had been paid on a "piece rate" — 20 pence a gland — so they now had no incentive for their unpleasant task. Pressure from hospital authorities on the workers, however, brought a response. Public mortuary workers also now receive nothing where they received 20 pence per gland before, so this may also be a factor in the HGH supply shortage. Negotiations are under way, says DHSS, on how these workers might be compensated by the area hospital authorities for providing the glands.

Some officials are suggesting that the real cause for the fall in supply is the "regularization" of collection procedures, compared with a little bit of horse-trading before. In the past, acetone sample bottles have been sent through the post, this is strictly illegal (acetone being inflammable) and has now been stopped. Also, extraction is now being done under full containment because of the danger of the propagation of slow virus from an infected gland (the pituitary being nervous tissue).

And were relatives always informed? Dr Lowry claims they were, and that he thus obtained more than half the pituitaries available from public mortuaries in London. The problems he lays squarely at the door of the DHSS. **Robert Walgate**

University of London Storm ahead

The reorganization of the University of London promises to be a more turbulent process than was foreseen a year ago. The plan that the Swinnerton-Dyer committee should make its final recommendations by the end of this year has been foreshortened by the mounting sense of urgency within the university. The committee has now agreed, with some misgivings, to produce its recommendations before the beginning of the next academic year. Meanwhile, the basis of the committee's interim report has been questioned by a document now circulating within the university, and likely to colour the arguments put by the Association of University Teachers to the committee at a meeting next week.

That document questions the arithmetic leading to the conclusion that the university's income will fall by between £15 and £20 million by the end of this decade. This is held to involve the unwarrantable assumption that the 3½ per cent cut in university finances announced last December will be permanent, the unnecessary assumption that overseas students attending London colleges will be charged only the minimum tuition fees decreed by the government and inconsistent assumptions about the basis used for calculating the loss of income if the numbers of overseas students decline. Briefly, the committee's calculation for the university as a whole is said to exclude the allowance made by the University Grants

Committee for part-time students.

This and other documents will form the basis on which the union will draw up a formal reply to the Swinnerton-Dyer committee's interim report, probably before the end of the month. Apart from arithmetical arguments, the union is concerned at the negative tone of the interim report, which is said to have neglected the university's advantages, in particular its attractions for overseas and part-time students and the relatively favourable age structure of its academic staff.

This view is likely to be echoed by the responses from individual colleges in the university, expected by Easter. Another view gaining ground is that the committee's interim report, with its comprehensive analysis of how the university spends its money, is sufficient, and that it should be for the university rather than the committee now to say what should be done.

The pitfalls for such committees are nicely illustrated by the troubles which have befallen the Flowers report on the organization of the medical schools in the University of London. After the rejection of the Flowers recommendations by the senate of the university last October, the

Joint Planning Board set up a working party to make a more detailed analysis of the costs of medical education in the University of London. The report, based on an analysis by a firm of professional accountants, suggests that the cost savings obtainable by closing various clinical and preclinical schools are not those forecast by the Flowers committee, and that none of the options so far discussed would yield as large a saving on the total cost of £32.8 million as a modest change in the staff-student ratio.

Chemical and nuclear weapons Scientists speak out

Two groups are being set up to give British scientists a stronger voice on the development of weapons of mass destruction. On 26 February, the Russell Committee Against Chemical Weapons, a branch of the Bertrand Russell Peace Foundation, launched a campaign against what is seen as a chemical arms race. And at the end of this month, a conference is being held at the Open University, Milton Keynes, to inaugurate Scientists Against Nuclear Arms, a group committed to providing scientific information on nuclear weapons.

Scientists Against Nuclear Arms says that it has already received several hundred letters expressing interest and support. And 19 signatures were attached to the appeal for names of those opposed to chemical weapons when it was launched last week. One notable signatory, Dr Frederick Sanger, not distinguished as a signer of petitions, is particularly concerned with the possible use of new techniques in biology to develop more sophisticated chemical weapons and with the distortion of research priorities that could result from a chemical arms race. These issues, and uncertainties about the British government's future policy, have prompted the appeal, which asks scientists not to take part in research on chemical weapons and the British government not to stockpile them.

Despite repeated assurances that there are no plans to store or manufacture chemical weapons in Britain, the appeal's organizers fear that the British government's policy may change in response to pressure from the new Reagan Administration to house stocks of new binary chemical weapons on European soil. Last year, the United States announced that it was building a plant to manufacture binary weapons.

Believing the present to be a time of uncertainty, the appeal's organizers say there is an urgent need for public and parliamentary debate. Scientists have an important role, they argue, because the development of chemical weapons could be influenced more directly than that of any other type of weapon by research in non-classified laboratories. **Judy Redfearn**

Soviet activists honoured

Three leading Soviet human rights activists have recently been honoured by Western scientific bodies.

The most prestigious award, foreign associateship of the French Academy of Sciences, was conferred on Dr Andrei Sakharov on 16 February. This, however, according to M. Paul Germain, one of the two secretaries of the academy, was in no way a political act, but was simply in recognition of the great importance of Sakharov's work in various fields of physics.

The Catholic University of Louvain in Belgium however, took a double view. When challenged by the Soviet embassy in Brussels that they should not award an honorary doctorate to Viktor Brailovskii, the Moscow refusenik cyberneticist, on the grounds that he was a "criminal and a prisoner" the rector replied that they were conferring the award in recognition of his contribution to the field of science and for maintaining the weekly seminars (for refusenik scientists).

Finally, the Royal College of Psychiatrists in London, in conferring an honorary fellowship on Dr Semeon Gluzman, did so specifically in connection with his work for human rights, for Dr Gluzman's chief contribution to psychiatry was the co-authorship (with Vladimir Bukovskii) of the *samizdat* "Handbook of Psychiatry for Dissidents" (a manual on how to resist psychological and pharmacological pressure), for which he is now serving a three-year sentence in Siberia following seven years in a labour camp.

CORRESPONDENCE

Data bank

SIR — The news item "Nucleotide sequences Too many banks" (*Nature* 15 January, p 112) implied that we do not yet have a nucleic acid sequence data bank in fact our data base system contains the largest collection of nucleotide sequences in the world, updated on a regular basis and accessed through a sophisticated computer retrieval system

The data bank was first made available to the scientific community by telephone link to our computer on 15 September 1980, when the information base contained over 227,000 residues of DNA and RNA sequences published before 1 August 1980. During a three month demonstration project, the collection was updated monthly with material published mainly between August and October. The final total on 12 December 1980 was 350,000 residues

We are continuing to update the data base and to make it available on a subscription basis. We are now processing more than 40,000 residues a month, and a book is being prepared which will include the information in the collection and describe the retrieval system and its uses

The data bank is supported by the Institute for General Medical Science of the US National Institutes of Health, the National Aeronautics and Space Administration, and contributions and subscriptions from foundations and industrial concerns. The expense involved in maintaining a complete, critically reviewed and up-to-date data base is too great for it to be operated on a voluntary basis, so other means of support must be sought. Our data base is available on a subscription basis (for the use of the subscriber in his own institution, not for redistribution). The collection will be made available on this basis to the European Molecular Biology Organization for use at Heidelberg, under the direction of Dr Greg Hamm, so that the interests of the European non-commercial research community can be considered

The cost of such a data base is usually justified by the resulting benefit to a research area. If all those organizations that could benefit from a nucleotide sequence data base were to contribute some support, there would be sufficient money to establish a continuing project

Antipodean 2,4,5-T

SIR — There is continuing concern in Australia regarding the possible deleterious effects of the herbicide 2,4,5-trichlorophenoxyacetic acid (2,4,5-T) on animal life, especially human beings. The question of a link between 2,4,5-T usage and congenital abnormalities has been raised on several occasions¹⁻³. Concerns of this nature were major reasons for withdrawing 2,4,5-T-based defoliants (such as Agent Orange) from use in the Vietnam war during the early 1970s. Many batches of defoliant

contained high quantities of the extremely toxic contaminant 2,3,7,8-tetrachloro-cyclo-dibenzo-*p*-dioxin, suspected of being a teratogen. International sale of the unused defoliant was apparently considered by the US government⁴ and some of this defoliant may have been imported into Australia⁵.

On 18 August 1971 the Australian government initiated enquiries under the provisions of the Customs Tariff (Dumping and Subsidies) Act regarding the importation of "salts of 2,4,5-trichlorophenol". Two years later, dumping duties were imposed on goods based on the esters and salts of 2,4,5-T, *retrospective* to 4 January 1971. It seems likely that large quantities of such goods were bought very cheaply overseas and sold on the Australian market in the late 1960s or early 1970s.

The chemicals 2,4,5-T and 2,4-dichloro-phenoxyacetic acid which make up the defoliant Agent Orange would normally be classified as pesticides in trade statistics. However, they could be given a chemical classification and assigned the 1972-3 SITC code number 512 28 09 ("other phenol derivatives, halogenated etc"). In the financial years 1969-70 and 1970-71 over 300 tonnes of chemicals with this SITC code are recorded in Australian trade statistics as imports from Singapore (the "country of production"). None of this material is listed as an export or re-export of Singapore in that country's *External Trade Statistics*, and there have been no subsequent imports from Singapore. (A small import from Singapore is recorded in 1968-69, but there is nothing before this.) The Australian Bureau of Customs has declined to be of any assistance in determining the true nature or origins of these goods.

With the help of the Australian Bureau of Statistics we have ascertained that in 1970-71, 290,000 lb of these imports entered Australia through Queensland, and another 22,400 lb through Western Australia. The *Australian Chemicals Guide (Industry Study)* shows a very limited number of companies involved in the processing of halogenated phenols. With the assistance of the *Guide* and the reference *Who owns Whom* it is possible to obtain a very short list of potential importers.

The Australian government has access to the records which would permit a thorough investigation of this matter. The results of such an investigation could have a vital influence on a multi-million dollar epidemiological study at present being undertaken by the Australian government on the effects of defoliants on Vietnam veterans. The study envisages a comparison of veterans exposed to defoliants with those "unexposed" veterans who did not serve in Vietnam.

Further details of this matter appear in a forthcoming paper⁶.

Cell contamination

SIR — The editorial, "Responsibility for trust in research" (*Nature* 22 January 1981, p 211) was excellent. Our group sends various human cell lines to laboratories all over the world. We caution scientists about the dangers of cell-cell contamination and if we read an article with strange conclusions that involved one of our many hundreds of cell lines, we offer to re-authenticate its identity without cost. Often the cell line in question has been passed from one laboratory to another. We have been discouraged to detect publications in which the scientists have continued to use a contaminated cell line even after the error has been pointed out to them. Biochemists in particular seem loath to seek biological advice. One chemist replied that the kind of cells that he used wasn't really important.

Actually there are other serious contaminations which affect research with cells. Most cell lines are cultured in media supplemented with antibiotics and often the cultures are contaminated with slow-growing bacteria and mycoplasma. It is difficult to detect minimal numbers of these organisms. Electron microscopy of a pellet of centrifuged media may reveal them.

We do not agree that the responsibility for monitoring the validity of research rests with the department head. Departments are too complex and even the division heads may not have the competence to evaluate a specific "bench" operation. The scientist himself and his associates in a "specialty" must exert the self discipline of avoiding, acknowledging and correcting errors.

As the use of enzyme profiles and new techniques of cytogenetics and the detection of "specific" antigens and cell products evolve, it will be easier to detect cell-cell contamination — perhaps even hybridization. Our methods for authenticating cells are still relatively primitive. The establishment of authorities to referee cell-cell contamination is premature. The donor and recipient of a cell line share the responsibility of the authenticity of the cell line.

Identification of a cell line should include (1) data about the original collection of tissue and pathological diagnosis, (2) serial numerical records of all subcultures, (3) electron microscopy — preferably of both the tissue of origin and the cultured cells, using special stains if critical, (4) isoenzyme profiles, (5) karyotype analysis of chromosome morphology after banding, (6) cell products, (7) studies of growth in immunosuppressed animals such as nude mice, and (8) growth characteristics in various media.

The errors associated with cell lines have probably had an infinitesimal effect on the fabric of scientific progress in comparison with other ridiculous and shameful pronouncements. For example, governmental carcinogens, the clinical effectiveness of interferon, and numberless epidemiological studies such as telephone surveys of complex disease states.

NEWS AND VIEWS

Carbon dioxide and climate: ice and ocean

from Starley L. Thompson and Stephen H. Schneider

THE presence of carbon dioxide in the atmosphere has long been known to affect climate through the so-called 'greenhouse' effect. The present rate of growth of atmospheric CO₂ concentration due to fossil fuel burning will result in a doubling of the CO₂ level sometime in the next century and this may produce a global surface temperature increase of between 1.5 and 4°C. Since this temperature change is as large or larger than any natural change in the past few millennia, the increasing interest in the connection between CO₂ and climate is not surprising. Recently, new ground has been broken in two relatively unexplored areas — the measurement of natural CO₂ variations on long time scales and the role of the ocean in modulating climatic response to the anthropogenic CO₂ increase.

The absence of firm evidence of past CO₂ variations has been a troublesome gap in our knowledge. A correlation between levels of CO₂ and palaeoclimatic temperature data would constitute the first clear empirical evidence of CO₂-induced climatic change.

Two recent papers have shown that past levels of atmospheric CO₂ concentration can be reconstructed from the CO₂ trapped in large ice sheets. Berner *et al.*¹ and Delmas *et al.*² have analysed trapped air in polar ice cores and concluded that large variations of atmospheric CO₂ occurred during the past 30,000 years. Previous attempts to analyse the total CO₂ content of the ice cores failed, but new extraction techniques increase the researchers' confidence that the measured CO₂ variations may reflect accurately the CO₂ variations in the atmosphere.

Two features stand out in the accompanying figure from Berner *et al.*¹ First, their data show a CO₂ concentration of as little as 200 p.p.m. by volume 10–30 years ago compared with a present-day value of around 340 p.p.m. Second, there appears to have been more atmospheric CO₂ in the mid-Holocene (about 5,000 years ago) than at present. Estimates from

current climatic models of the global surface air temperature change caused by such CO₂ variations are also shown. Uncertainties in present climatic theory suggest that these temperature estimates should be within a factor of two of the actual CO₂-induced temperature changes — assuming, of course, that these preliminary measures stand up to further analysis. Note that the estimated global temperature changes range from +1.8°C to –2.2°C. These represent a large fraction of the temperature range deduced from other palaeoclimatic evidence for the period.

Graph showing the relationship between the atmospheric CO₂ level reconstructed from Camp Century, North Greenland, core measurements (upper curve) and the corresponding global change in surface air temperature estimated from current climatic models (lower curve) (Taken from ref. 1).

Should these large CO₂ variations prove to be reasonably accurate, the implications for palaeoclimatic theory would be enormous. One of the most difficult problems in palaeoclimatic modelling has been the determination of the feedback processes which must exist to cause the large-amplitude glacial to interglacial transitions.³ A feedback including natural CO₂ variations like those in the figure could explain as much as half the surface temperature amplitude of the ice age/inter-

glacial climate changes. However, it does not appear that the CO₂ variations initiate these large climate changes as the minimum and maximum CO₂ concentrations do not appear to lead the respective glacial and interglacial extremes of 18,000 and 6–8,000 years ago. Therefore, CO₂ changes may act only to amplify climate changes that are initiated by other means.

In addition to improving our understanding of past climates, any evidence that CO₂ levels were higher during the mid-Holocene than today may give more credence to the idea of using this climatic 'optimum' period — when surface temperatures were a few degrees warmer than today — as an analogue for the climatic change which may be induced by a future anthropogenic CO₂ increase.⁴

A new area of research on the CO₂ problem has been recently explored by Hoffert *et al.*⁵ Previously, most climatic modelling studies examining the effect of increased CO₂ have considered the models' response in a state of climatic equilibrium. For example, a researcher would perturb a mathematical model of climate with a fixed, time-independent doubling of the CO₂ concentration and allow the model climate to reach a new equilibrium. This is a reasonable approach to take when testing the various models since it affords an order-of-magnitude estimate of climatic response for a fixed forcing (for example, when the CO₂ concentration has doubled), while meeting the constraints of a limited computing budget. However, the actual CO₂ increase is a continuous rise, not an instantaneous step increase. In addition, because of its large heat capacity, the ocean acts as a thermal buffer by delaying the response of the atmospheric temperature — an effect that has been neglected or undervalued in most equilibrium studies.

In order to simulate adequately the climatic response to the actual time-dependent CO₂ increase one must account for oceanic heat capacity, which means that one must determine how the ocean mixes the excess CO₂ heating at its surface. The upper layer of the ocean is mechanically well mixed by surface winds to a depth of approximately 50 metres. Including the heat capacity of the mixed layer alone would delay the global temperature response to the CO₂ increase.

Starley L. Thompson is in the Department of Atmospheric Sciences, University of Washington and Stephen H. Schneider in the National Center for Atmospheric Research, Boulder, Colorado

by 5 to 10 years^{6,7} But the mixed layer is only a small fraction of the ocean volume. Mixing occurs throughout the depth of the ocean, although at much slower rates than within the mixed layer. When Hoffert *et al* simulated the heat capacity of the entire ocean in an ocean model with vertical diffusion and specified upwelling, they found that the response of the global temperature to the CO₂ increase would be delayed by 10 to 20 years by the year 2,000. Even longer lags would occur in the next century.

The effect of such a global time lag will have to be considered when examining

future climatic data for the predicted CO₂ warming. We may not be able to extract a detectable CO₂ 'signal' from the climatic 'noise' (ref.8) until several decades after the date estimated from equilibrium calculations. Thus the absence of unambiguous warming during the remainder of this century would not serve to disprove the validity of our current equilibrium estimates of the effect of CO₂ on global temperature.

However, the determination of the global temperature time lag cannot be divorced from the complex problem of modelling the regional variations in oceanic mixing. As much of the communication between the deep ocean and surface waters occurs in downwelling polar seas, Hoffert *et al* concluded that the as yet poorly understood response of the polar oceans to the CO₂ increase may be very important in determining the global time lag.

A related idea (discussed by Schneider and Thompson⁹) is that variations in oceanic mixing which create a geographical distribution of effective oceanic heat capacity may also serve to produce thermal time lags with substantial regional

variations. The significance of this goes beyond the added difficulty in unambiguous early detection of the global CO₂ warming. Different thermal lags for different regions implies that anomalies in surface temperature gradients, and any associated regional climatic anomalies, may with time become substantially different from those computed in an equilibrium simulation. Since it is the potential regional climate changes which are of the most economic concern, we feel that improving our understanding of the nature of the transient climatic response should be a major priority for future CO₂-climate research. This means more coupled atmosphere-ocean-cryosphere modelling studies.

Finally, we should point out that the problem of the transient climatic response is just one of a set of interdisciplinary problems. How much fossil fuel will be burned, the global carbon cycle, the global and regional equilibrium climatic response, the transient response, the physical and societal impacts of climatic changes, and possible policy responses to prevent or adapt to CO₂ effects are all important aspects of the 'CO₂ problem'. □

Active galaxies: dragon hunting in Arizona

from Martin Elvis and Andrew S. Wilson

PLOTS of the electromagnetic spectrum of active galaxies covering the ten decades of frequency from radio waves to X rays were described at a recent workshop* and show just how rapidly this field is advancing. The successes of the radio astronomers' Very Large Array (VLA) and the HEAO X-ray observatories enabled radio and X-ray astronomers to meet their optical colleagues on nearly equal terms for the first time. The sensitivity and angular resolution of the new instruments is bringing some order into the classification of active galaxies — the old diversity now appears to have been largely the result of observations limited to only the extreme examples of particular characteristics.

The meeting was restricted to active galaxies and conspicuously avoided their close relatives, quasars. As a result there was an emphasis on objects in which resolved structure could be seen. The most striking examples of this came from the detection of over 50 jets by the VLA (reviewed by Bridle, VLA, New Mexico). These long, collimated structures point from the nuclei of bright radio galaxies to their giant radio lobes. They needed a dynamic range approaching 1,000:1 to be discovered close to the bright nuclear sources but, now that this has been achieved, observations of such jets have

become common, almost ubiquitous. Over 60 per cent of the nearby ($z < 0.05$) 3CR radio galaxies have them. The jets are seen on all size scales from 1 parsec to 1 Megaparsec. Often they are one-sided, perhaps as a result of relativistic beaming. In all likelihood we are seeing the beams of relativistic particles which Rees proposed ten years ago would power the giant radio lobes. Polarization measurements show that the magnetic field is often parallel to the jet near the nucleus but turns at right angles to the jet further out (although sometimes leaving a parallel region at the edge). There is a suggestion that the parallel region is longer for higher radio core luminosities. If such a correlation is borne out it will provide useful information for the beam instability models discussed by Blandford (Caltech), Laing (NRAO, Virginia) and van Bruegel (Leiden).

It is necessary that the jets are confined in some way. The simplest possibility is that the galaxy and the jet are surrounded by hot gas. This should be visible by X-ray emission and observations have been made from jets in the three classic sources: M87, Cen A and 3C273 (Schreier, Harvard-Smithsonian Center for Astrophysics). However, the detailed correspondence of the X-ray, optical, and radio features suggests strongly that the X rays are a continuation of the jets synchrotron spectrum. For other 3CR radio galaxies initial results of the *Einstein* survey

(Fabbiano, Harvard-Smithsonian Center for Astrophysics) require equipartition fields within the jets of the order 10^6 – 10^7 gauss. If these radio jets are thermally confined the expected X-ray emission from the confining gas is just below the current detection threshold.

Miniature double sources have been found by Wilson (University of Maryland) in five Seyfert 1 galaxies. Type 1 Seyferts are the archetypal 'radio-quiet' active galaxies so this discovery is particularly interesting. It demonstrates that the same linear symmetry we see so clearly in the radio-loud case applies to this other, much more numerous, class. Since these Seyfert 1 galaxies have clear spiral structures it is simple to see whether the direction of radio symmetry aligns with the rotation axis. Such convenient alignment does not appear to occur.

Before leaving jets the extragalactic astronomers were presented with a 'working scale model' of their problem. Hjellming (VLA, New Mexico) presented a beautiful series of VLA observations of SS433 showing a complex series of changes with time. He was able to explain these with a simple, constant velocity, ballistic blob model. Whilst this is surely too simple for the extragalactic case it must have some

Martin Elvis is in the Center for Astrophysics, Cambridge, Massachusetts and Andrew S. Wilson is in the Astronomy Program, University of Maryland.

*A workshop on active galaxies was held in Tucson, 19–23 January 1981 and was sponsored by the Kitt Peak National Observatory.

suggestive power for those trying to understand the larger scale phenomenon

The other three days of the meeting were used to examine and compare observations of the compact nuclei themselves. Weedman (Pennsylvania State University) presented a useful criterion for distinguishing the emission line galaxies that need a non-thermal ionizing continuum from those that can be explained solely by bursts of star formation. He found that for emission line widths greater than 250 km s^{-1} at least 90 per cent of galaxies needed, as he said, 'a Dragon in the middle' — a general term for any source of a non-thermal continuum. For narrower line widths no dragon is needed.

Far from being discarded for their lack of activity narrow line 'starburst' nuclei emerged as a new area of study with radio (Gisler, NRAO, Virginia), $\text{H}\alpha$ emission line (Heckman, NRAO, Virginia) and X-ray (Fabbiano, Harvard-Smithsonian Center for Astrophysics) images providing new inputs. Why some galaxies undergo intense star formation periods is as little understood as why other galaxies have non-thermal active nuclei.

Further clarification of what constitutes an active nucleus came from comparing the X-ray (Mushotzky, Goddard Space Flight Center) and optical (Huchra, Harvard-Smithsonian Center for Astrophysics) luminosity functions for active galaxies.

These now agree (to a factor two) so the two selection techniques — hard X-ray emission and broad optical emission lines — do find the same population of objects.

The 'narrow emission line galaxies', once thought to be a different class, have the universal power law X-ray spectrum of slope 0.7 above 4 keV that all measured Seyfert 1 galaxies possess (Mushotzky). Also, better optical spectra showed faint broad wings on their Balmer lines, just like Seyfert 1 galaxies.

Some anomalies remain. No-one is sure whether or not Type 2 Seyfert 1 galaxies (differing from Seyfert 1 galaxies by the absence of broad hydrogen emission lines) have dragons in them. Also new Einstein identifications of active galaxy sources (Elvis, Harvard-Smithsonian Center for Astrophysics), include two that would not have been picked out by an optical survey since they have neither strong emission lines nor blue colours.

Much detailed theoretical work was presented, largely based on the concept of an accretion disk around a supermassive black hole. Although progress is being made in investigating these systems as demonstrated by, for example, Begelman (Berkeley), Duncan (Cornell) and Eilek (Institute of Mining and Technology, New Mexico), the models need to be explored further before the tenuous links between theory and observation can be strengthened. □

the presence of SV40 T antigen and that it occurs irrespective of whether the SV40 sequences are physically linked to the foreign DNA or merely co-injected with it.

The chief reasons for using viral vectors are to place foreign DNA sequences under the control of known viral regulatory elements, and to attach them to viral origins of replication so that the ectopic sequences can be amplified to high copy number in infected cells. Viral vectors have the further advantage that the foreign DNA can be delivered virtually synchronously to large populations of cells. Until recently, only one type of viral genome — that of SV40 — was used for this type of work. Typically, the late region of the viral DNA is replaced in whole or in part by foreign DNA sequences. Unlike bacteriophage λ vectors where the recombinant DNA molecules are packed *in vitro* into virus particles, the SV40-chimaeric DNAs are first mixed with a helper viral DNA and the mixture then used to infect permissive cells. Although only a small proportion of the cells can be infected with DNA, the susceptible cells efficiently take in both the recombinant DNA and its helper. The recombinant genome replicates and as long as it is not too large, becomes packed into viral particles. The resulting mixed virus stock can be used to infect enough cells to allow analysis of the expression of the foreign DNA by conventional biochemical techniques. Quite a large number of genes has now been propagated and expressed in this way. The most recent additions to the list are human growth hormone, hepatitis surface antigen, human genomic globin sequences (Pavakis, NIH) and the putative transforming protein, p21, coded by Harvey sarcoma virus (Khoury, NIH). In many cases the expression of the exogenous genes is surprisingly efficient, even when the foreign DNA is inserted into unpromising positions in the SV40 genome. For example, when a form of the rat preproinsulin gene from which all splice signals have been deleted is inserted into an SV40 vector which also lacks splice signals, recombinant mRNA is synthesized in large quantities under the control of the SV40 late promoter and translated efficiently (Gruss, NIH, see *Proc natn Acad Sci USA* 133; 1981). This result indicates that lack of splicing may not be as strong a deterrent as had previously been thought to the expression of ectopic DNAs.

Promising though the SV40 system is, it has suffered from two disadvantages. First, virus populations which contain recombinant genomes are always mixed, and sometimes the particles which carry foreign DNA sequences form only a small proportion of the virus stock. Second, the size of the foreign insertion is limited by the amount of DNA which can be packed into SV40 particles. However, several new vectors are being developed which promise to alleviate these difficulties. Bovine papilloma virus is capable of transforming

Designer genes

from a correspondent

SMALL MEETINGS on molecular aspects of biology are rare luxuries these days. Almost as fast as they well up, new ideas and discoveries become part of the mainstream, where they sustain shoals of workers most of whom are darting in the same direction at the same time. Consequently, it was refreshing to attend a small meeting* on 'Mammalian Vectors' during which the forty or so participants discussed work in varying stages of accomplishment which dealt, in surprising variety, with the problems of obtaining expression of ectopic genes in mammalian cells.

There are three methods in common use by which foreign genes (generally in the form of cloned fragments of genomic DNA or cDNA copies of mRNA) can be reintroduced into cultured mammalian cells: by microinjection, linked to segments of viral DNA, and by simultaneous transformation with two separate pieces of DNA — one carrying the gene of interest, the other a genetic marker which confers a

selective advantage on the recipient cells.

Each method has its own set of advantages and disadvantages and the three techniques therefore should be regarded as complementary rather than exclusive. Microinjection is an efficient way of introducing known quantities of DNA into cells whose exact location on the culture dish is known. Enough cells can be injected to allow detection by immunofluorescence of the products of expression of the injected DNA. Normally such expression is transient, lasting, at the most, for a few days. However, about one to two per cent of the injected cells can be developed into lines which express the foreign genes constitutively (Capecchi, University of Utah, Lo, University of Pennsylvania, French, Anderson, NIH). Furthermore, Capecchi showed that the efficiency with which constitutive cell lines are established can be increased some 20-fold, by injecting together with the foreign gene, a segment of DNA which spans the origin of simian virus 40 (SV40) DNA replication. The cause of this improvement is unknown, it is especially puzzling that the effect does not depend on

*Held from December 11 to 13 at the Banbury Conference Center of Cold Spring Harbor Laboratory.

mouse cells to yield cell lines which, by contrast to similar cells transformed by SV40, contain 10–120 copies of circular viral DNA with no evidence of integrated viral sequences. Howley (NIH) has attached the rat preproinsulin gene to the transforming region of bovine papilloma virus DNA and has established transformed cell lines which contain episomal copies of the recombinant DNA. The cells contain spliced preproinsulin mRNA and secrete significant quantities of proinsulin.

Gluzman (Cold Spring Harbor Laboratory) has developed lines of permissive simian cells which constitutively express functional SV40 T antigen. They can therefore be used in the absence of helper to propagate recombinant SV40 molecules in which the early region of the viral genome has been replaced by foreign DNA sequences, or to amplify DNA molecules which carry the SV40 origin. Using this system, Mellon (California Institute of Technology) has attached to the SV40 origin cloned copies of human chromosomal globin genes. Forty-eight hours after the introduction of these chimaeric molecules to COS cells, the globin genes direct the synthesis of approximately 10^4 molecules of globin mRNA per cell. The mRNAs are spliced, polyadenylated and have 3' and 5' ends identical to those of normal globin RNA. These results show that cloned copies of chromosomal genes which carry their own control sequences and which normally are active only in specialized cells can be efficiently expressed when reintroduced to undifferentiated tissue culture cells and amplified to high copy number as part of an SV40 recombinant genome.

Two groups (Thummell, University of California, Berkeley; Solnick, Cold Spring Harbor Laboratory) have used defective adenovirus 2 genomes to propagate and express foreign DNA. Using different techniques, both groups have constructed a series of recombinants in which the expression of the early region of SV40 is placed under the control of the major adenovirus late promoter. Many of the recombinants synthesize large quantities of authentic SV40 large T antigen. This result opens the way to use of adenovirus as a vehicle for the propagation and expression of moderate-sized eukaryotic genes, as, at least in theory, adenoviral vectors can be constructed which are able to accept segments of foreign DNA 30–35 kilobases in length.

Finally, although other selective markers are being developed (methotrexate resistance, neomycin resistance, dependence on guanine phosphotransferase; Southern and Subramanian, Stanford University), thymidine kinase, cloned either from herpes simplex virus or from chicken DNA, remains the marker of choice in co-transformation experiments. Using this technique, there is no difficulty in obtaining cell lines which contain a few copies of the foreign DNA of interest, in

the form of a large catenate formed by recombination between the incoming thymidine kinase gene, the carrier DNA and the foreign sequences themselves (Wigler, Cold Spring Harbor Laboratory, Ruddle, Yale). In general the level of expression of the foreign sequences is too low to be useful. Nevertheless, the system can be manipulated in interesting ways. For example, Kurtz (Cold Spring Harbor Laboratory) reported that the α -2 μ globulin genes which code for the major

urinary protein of rats can be introduced by co-transformation into cultured mouse cells. Several cell lines were obtained in which these foreign genes could be turned on by dexamethazone. The finding that co-transformed genes can continue to respond to hormones opens up the exciting possibility of analysing hormonally controlled genes by the same techniques that have been so successful in dissecting the fine structure of other viral and cellular promoters. □

Astrophysics and particle physics come together

from Frank E. Close

THE advances made in high-energy physics and astrophysics have enabled the 1970s to be described as the greatest ever in fundamental research. The discoveries of the J/ψ particle in 1974 and of charm in 1976 provided major evidence supporting the theory that united the electromagnetic and weak forces. Some of these particles' properties caused attention to be focused on a candidate theory of quark interaction, named 'quantum chromodynamics' or simply QCD. (The so-called 'strong' nuclear force is now viewed as a complicated manifestation of this more fundamental QCD force which acts on the quarks — the constituents of the subnuclear particles.) Although still some way from being verified, accumulating data do appear to fit in with theoretical expectations based on QCD.

The mathematical similarities among the theories of the electromagnetic, weak and 'strong' forces are so striking that theorists have tried to build a grand unifying theory which would include all the natural forces except gravity. The simplest way of implementing the theory has already successfully predicted the existence and mass of the fifth variety of quark (the so-called 'bottom' quark). Much experimental effort is now centred on the prediction that protons are unstable.

These topics were all reviewed at the annual meeting of the UK High Energy Theoretical Physicists held in December at the Rutherford and Appleton Laboratories.

J. Badier (Paris) reviewed experimental data on the behaviour of quarks inside protons and pions and together with R. Roberts (Rutherford Laboratory and CERN) discussed how well these and other data fit with the QCD theory of quark interactions. The answers continue to be very encouraging. Everything seems to fit with the theory, and although far from proved one increasingly feels that it would. *F. E. Close is at the Rutherford and Appleton Laboratories, Didcot, UK.*

now require something totally unexpected to overthrow it.

Although the basic tenets of QCD are rather simple, the rich structure arising from them is still only poorly understood. M. Creutz (Brookhaven, New York) described some computer-based studies of QCD performed on a 'lattice' (where space-time is treated as discrete rather than as a continuum) which suggest that QCD leads to confinement of gluons (the QCD quanta, analogues of photons in QED) and thus, it is speculated, of quarks. Direct proof of this is still, however, unavailable. Some technical problems on the behaviour of QCD in the IR region were discussed by J. C. Taylor (Cambridge). Some feel that deeper understanding of this domain might resolve the confinement question.

Looking to future developments, searches for proton decays and their significance for grand unified theories of the natural forces were discussed. D. Perkins (Oxford) described the experiments planned or in operation. Present limits show that the proton lifetime is greater than some 10^{29} years. Perkins pointed out that logistic problems with experiments deep underground and with backgrounds from neutrinos would probably prevent this limit ever being pushed beyond 10^{33} years. Grand unified theories predict 10^{31+2} years — satisfyingly in this window! Observation of such proton decays in the near future could provide a major impetus for belief in grand unified theories.

The theoretical issues involved in constructing grand unified theories of the particles and forces were detailed by J. Ellis (CERN). In our cold world, energy densities are rarely much greater than 1 GeV per fm³ and the forces appear quite different from one another in their strengths and properties (see Dombey *Nature* 288, 643, 1980). The unification of the forces is manifested at energy densities some 10^{15} times greater than these (note

that gravity is not important until densities of yet a further 10^4 are met, and so gravity can still be ignored) High-energy accelerators of subatomic particles can create locally energetic conditions and do appear to show a glimpse of the trends required if QCD is to be unified with the electroweak force, but we are still many orders of magnitude from 10^{15} GeV. However, such energy densities were probably common in the early Universe and it is here that a new merging of interests in high energy and astrophysics is taking place. These were described by Ellis and R. Taylor (Sussex)

Proton stability is particularly significant as several years ago Andrei Sakharov (Gorki) had noted that three ingredients were required if we were to understand the apparent excess of matter over antimatter in the Universe at large. One is an absolute distinction between them: this is indeed provided in nature by the phenomenon of CP violation (whose discovery led to the 1980 Nobel prize for Cronin and Fitch of the US). The second is an absence of thermal equilibrium provided in modern cosmology theory by the big bang expansion. Finally, proton instability is required. This is indeed provided by the grand unified theories; we wait to see if it is also provided by nature!

Within the grand unified theories it has been argued that mechanisms naturally exist that will give rise to the observed quantitative matter excess. Ellis pointed out that the validity of this 'explanation' can be tested because the mechanism also generates an electric dipole moment for the neutron. At present there is an experimental upper limit that places this moment at less than about 10^{-24} e cm. Present experiments hope to lower this by three orders of magnitude. Ellis noted that the above theories provide a 'cosmological lower bound' some four orders of magnitude below the present limit! This should provide a significant spur to experiment and provides another example of how studies of subnuclear particles can reveal the mechanisms responsible for the development of the early Universe.

One of the more recent lines of investigation is into the question of whether there are new phenomena between the present energies and 10^{15} GeV (apart from the predicted production of massive W, Z particles of the electroweak theory and the postulated sixth quark and Higgs particles). In particular, the nature of the Higgs particles is unclear.

During the past year there has been much interest in the possibility that the Higgs particles are not elementary but are dynamically bound composite systems of more fundamental entities. E. Eichten (Harvard) described so-called 'hypercolour' or 'technicolour' theories that contain the Higgs particles as composite bound states and in some formulations require substructure to the leptons and quarks. These theories predict that a new ultra-

high-energy scale of phenomena exists in nature. Eichten described possibilities of testing these ideas at present energies. Experimentalists are urged to search for the light pseudo-Goldstone bosons predicted in the theory (possibly of a mass of about 10–20 GeV and producible in electron-positron annihilations) or to search for the rare decay modes that technicolour's existence can induce from the conventional particles (like $\mu \rightarrow e\gamma$, $K \rightarrow \mu e$).

Finally, in all these brave schemes to unify our understanding we come up against the perennial problem — gravity. How gravity fits into nature's scheme is still

something of a mystery. P. van Nieuwenhuizen (Stony Brook, US), one of the founders of 'supergravity' theory, described developments in this exciting field. Some of the technical problems that arise attempts to build a satisfactory quantum theory of gravity appear to be overcome if gravity is but part of a larger theory — supergravity. This theory is very elegant mathematically and yet, frustratingly, we have little or no indication that Nature has made use of it. van Nieuwenhuizen succinctly summarized the beauty of the mathematical structures by saying "I hope that Nature is aware of our efforts" □

Υ physics—from bottom to top

from Roger Cashmore

THE Υ meson was first observed in proton-proton collisions late in 1977 at Fermi National Accelerator Laboratory (FNAL). The meson had a mass of ~ 9.45 GeV and was seen in its decays to $\mu^+\mu^-$ and e^+e^- with a width consistent with the measurement resolution. (The width of a resonant state is related to its lifetime. Very short lifetimes lead to large widths. However, even a narrow state can appear to be broad if the experiment is limited by the measurement accuracy. The width then reflects the experimental resolution.) A further state, the Υ' , was also indicated at a mass of ~ 10.00 GeV.

These observations were quickly confirmed in experiments at the e^+e^- storage ring, DORIS, at DESY in Germany. The Υ and Υ' were observed as separate states, ~ 580 MeV different in mass, and since then the Υ has been shown to have a total width of 20–50 keV, a remarkable fact for such a high-mass state and rather reminiscent of the ψ . Generally, states of such high mass decay quickly into many lower-mass particles leading to large intrinsic widths of hundreds of MeV. Combined with the FNAL data, these accurate measurements of the masses of the Υ and Υ' states suggested the existence of yet a third Υ resonance at a mass just beyond the reach of the DORIS storage ring.

It appeared that the bound state system of a new quark, the charge $\frac{1}{3}$ bottom quark (b), and its antiparticle ($\bar{b}$) was being observed. The Υ was the ground-state $b\bar{b}$ meson and the Υ' its first excited state. New quarks, bottom (charge $\frac{1}{3}$) and top (charge $\frac{2}{3}$), had been implied by the earlier observation of a new lepton, the τ lepton, at the electron-positron storage rings SPEAR and DORIS, capable of reaching 7 and 10 GeV energies respectively.

The past year has seen the successful operation of a new electron-positron storage ring, CESR, at Cornell which can be used for experiments in the 8–16 GeV mass region. This covers the Υ mass range and allows much more detailed studies of this new quark system. The Υ

and Υ' states were confirmed and the third state, the Υ'' , observed at a mass of ~ 10.32 GeV. All three states had widths consistent with the machine resolution, suggesting that they were all narrow resonances.

However, as the beam energies were raised a fourth structure, the Υ''' , was observed at a mass of ~ 10.54 GeV but this had a width of ~ 10 MeV, larger than the machine resolution and in marked contrast to the other states. This suggests that the state is above the threshold for decay into $B\bar{B}$, B being a $b\bar{q}$ meson (where q is one of the more familiar u, d, s quarks) carrying the flavour of the new b quark. Thus these Υ states provide a laboratory for the study of both the bound systems of this quark, $b\bar{b}$, and the open flavour states $b\bar{q}$.

These two areas are vital in validating the present descriptions of the forces in particle physics. The strong force, which binds the quarks and antiquarks to form the mesons, is hypothesized to be indifferent to the quark flavour and only related to their colour through the exchange of coloured gluons between them. (Earlier results had indicated the need for three colours of each flavour of quark.) Hence $q\bar{q}$ systems should be similarly independent of the quark flavour. This model for the strong interaction is known as QCD (quantum chromodynamics). On the other hand, the weak force, now believed to be unified with the electromagnetic interaction according to the gauge theory of Weinberg and Salam, implies specific transitions between the different flavours of quark, for example, $c \rightarrow s$, $s \rightarrow u$. These hypotheses need quantitative verification.

In the $b\bar{b}$ bound system the mass difference of the Υ and Υ' is close to that of the ψ and ψ' , indicating that, although the new quark has a mass ~ 5 GeV in contrast to the charm quark mass of ~ 1.5 GeV, the quark forces (or potentials) are essentially

Roger Cashmore is in the Department of Nuclear Physics, University of Oxford

unaltered. This is the remarkable result, that the force is flavour independent, which is expected if the strong forces are indeed due to the exchange of coloured gluons as embodied in QCD.

These narrow states, too low in mass to decay to $b\bar{q} + \bar{b}q$ mesons, are further expected in QCD to decay by the emission of three gluons (the smallest number allowed by a variety of selection rules). Detailed analysis of the hadronic final state of the T indicates that even this prediction is consistent with all of the observations. Thus this T system confirms dramatically the QCD model of strong interactions.

The T'' should be a prolific source of B mesons, and hence detailed studies of their properties (and those of the b quark) will be possible. A B meson has yet to be demonstrated at Cornell (an earlier possibility from a CERN experiment has since disappeared with further data). Its decay modes are many and the multiplicity of particles in each is expected to be very high, making a clean identification difficult. Nonetheless, it is possible to look for irregularities that might be associated with the T'' and hence the B particles. An excess of K mesons is observed and these are expected if the b quark (within the B meson) undergoes a weak decay transition to the charm quark, which has a well documented predilection for strange particles in its decay. The excess is, within the large errors, just what would be expected. Furthermore, the semi-leptonic weak decays of the B mesons ($B \rightarrow \nu e \nu$, where ν represents one or more hadrons) lead to increased numbers of electrons and muons. Such increases are observed and the inferred branching ratios for these decays are 24 ± 6 per cent, whereas the standard model, containing a top quark, would suggest a value of ~ 34 per cent, not widely inconsistent with the experimental value. Thus the data, sparse as they are at the moment, suggest that the standard model remains intact with the most likely existence of a top (charge $\frac{2}{3}$) quark and a weak decay chain $t \rightarrow b \rightarrow c \rightarrow s$. Higher energies than those achieved so far at PETRA (~ 38.6 GeV) will be needed in the search for this quark. A very recent paper (S. Glashow *Phys. Rev. Lett.* **45**, 1914, 1980) puts forward further theoretical arguments for a mass of 38 ± 2 GeV for the top quark. Experimentalists should soon be able to check on this. The present gauge model relies on its existence. The new facilities in Cornell will undoubtedly produce far more quantitative results in the future. These will allow more systematic tests of our current ideas of the quarks and their strong and weak interactions and perhaps in this quantitative exposure new possibilities will emerge. After all, we have as yet no explanation for the number of generations of quarks and leptons. Experiments will perhaps one day provide the clue. An exciting few years are in store at Cornell. $\square$

Molecular hydrogen in T Tauri

from Stephen P. Maran

THE discovery of ultraviolet molecular hydrogen emission in T Tauri with the International Ultraviolet Explorer satellite (see Brown *et al.* this issue of *Nature* p 34) has considerable potential for three fields of research: the nature of T Tauri stars and their associated nebulae, the formation and development of the Solar System, and the study of molecular hydrogen in the Galaxy. T Tauri stars have masses about equal to that of the Sun, but are rotating much more rapidly and are thought to be stars still-in-the-making, only about a million years old and still contracting towards the Main Sequence. Some appear to be losing mass, the so-called 'T Tauri wind', while others appear to be still accreting matter from the surrounding nebulae. It is widely accepted that the Sun passed through a T Tauri phase and models of Solar System formation take into account the postulated high wind and luminosity and the concomitant decreasing gravitational attraction of the early Sun to solve a number of problems. Among them are the placing of Mercury and perhaps other planets into their present orbits, the sweeping out of excess gas and dust in the protoplanetary nebula, the dispersal (in modern versions of the Laplace nebular hypothesis) of gas rings in the planetary orbits, the formation of chondrules found in meteorites, and the reduction of the Sun's rotation to its present very low rate. T Tau itself, the prototype of the stellar class, is associated with a small luminous cloud called Burnham's nebula.

It had been thought unlikely that ultraviolet emission known to occur in nebulae would be detectable in Burnham's nebula with instruments having the sensitivities of the two IUE spectrographs. Brown *et al.* confirmed this, for they found no previously known nebular lines in the spectrum of the object, but instead discovered emission in the H_2 Lyman bands that previously were seen only in sunspots. In recent years, astronomers have concluded that the interstellar gas is not dominated simply by atomic hydrogen but that there is also a substantial molecular component. This has been largely inferred from observations of the CO molecule in the galactic plane but H_2 in the general medium has also been seen through its ultraviolet absorption lines (a technique feasible only in the directions of appropriate hot stars that serve as background continuum sources), and H_2 in several nebulae (including Burnham's nebula) has been found via the infrared

vibration bands. More recently, a bound-free absorption continuum of the H_2^+ ion has been detected in planetary nebulae (S. Heap and T. P. Stecher *Proc. Conf. on the Universe at Ultraviolet Wavelengths* 1980).

Brown *et al.* distinguish between two mechanisms for H_2 excitation in Burnham's nebula and favour the 'shock excitation' model. The nebula is much smaller than the Oort cometary cloud that surrounds the Sun, and hence phenomena on its scale may well be relevant to the early evolution of the Solar System. Since H_2 must be a principal component of the nebula, observations with more sensitive ultraviolet instruments having very fine angular resolution (notably, the High Resolution Spectrograph now under development for flight on the *Space Telescope*) will enable astronomers to investigate the dynamics of the shocked gas. In the meantime, nebular specialists will be busy calculating where else in the Galaxy this new diagnostic may be detectable. $\square$

Planarian neoblasts

from J. Baguña

IN a News and Views article on 21 August 1980 Jonathan Slack¹ reviewed briefly the sources of the cells involved in regeneration in planaria and, in doing so, made several assertions that deserve comment.

(1) 'Neoblasts' are indeed small basophilic cells present in planaria. But to think of them as cells 'reserved' for regeneration is equivocal since many planarian species, having sexual reproduction, never regenerate in nature. So what are the neoblasts for? The answer lies in considering the neoblast not just as a 'reserve' cell but as the stem cell of most differentiated cell types supplying transit cells to balance the death of cells.

(2) In planarian regeneration it is meaningless to argue whether neoblasts come from all parts of the body or from local tissues through metaplasia because the blastema can be formed (and is formed) from pre-existing local neoblasts proliferating near the wound. Moreover, Wolff's experiments², which have been cited as evidence for migratory neoblasts, have been consistently criticized³⁻⁶ because at most, they only show the 'repopulation' of the irradiated region by healthy neoblasts through cell division and do not prove a direct migration of neoblasts from unirradiated regions to the wound.

(3) Slack points out that "histological and electron microscopic studies suggest that local dedifferentiation does occur." The

Stephen P. Maran is Senior Staff Scientist in the Laboratory for Astronomy and Solar Physics, NASA-Goddard Space Flight Center, Maryland.

J. Baguña is in the Department of Genetics, University of Barcelona, Spain.

available evidence is scanty and unclear so this seems a bold assertion. Other authors^{7,8} have been unable to find any dedifferentiating features in any of the blastema constituting cells.

(4) The results reported by Gremigni and Miceli⁹ supporting cell dedifferentiation and transdifferentiation in planarians, though offering new ways to re-evaluate the problem of blastema formation, are not as conclusive as has been suggested. First of all, the sequence proposed: germ cell → blastema cell → muscle cell, and its corollary of dedifferentiation and metaplasia are not necessarily related as the loss of an haploid complement during spermiogenesis, though one of the first steps from neoblasts to male germ cells, is only a trivial phenomenon regarding cell determination. Unless spermatids or primary spermatocytes are shown to give rise to blastema cells, and then to differentiated cells, we cannot talk properly of dedifferentiation and metaplasia. At the most, this would qualify for dedetermination (or trans-determination) and the sequence proposed should be read instead as predetermined or determined: germ cell → blastema cell → muscle cell. Second, and more important, the sequence suggested by Gremigni and Miceli, if proved correct, has to be demonstrated for other differentiated cell types since several planarian species, being asexual, lack germ cells. Besides, it is possible, as suggested by Betchaku⁴ and Pedersen⁸, that both processes (neoblasts and metaplasia) occur during planarian regeneration. If this were the case, the important issue would be to know the partitioning between both phenomena during planarian regeneration.

(5) Though most (but not all, witness *Hydra*) regenerative phenomena in the Animal Kingdom have been proved to occur through cell dedifferentiation and re-differentiation, the present trend to extrapolate this mechanism to all animal groups (including planarians) overlooks the possible relationship between the actual mechanism of regeneration and the complexity of the species. Planarians are one of the most primitive acoelomates, and their tissular complexity is rather low if compared with other epimorphic-regenerating organisms like Amphibia or Insecta. No wonder that dissimilar mechanisms may operate during regeneration in these groups. The planarian neoblast system, based on a unique and multipotential self-renewing stem cell, though appropriate to the low-level complexity of planarians, is clearly

inadequate for organisms with static (decaying) cells and transit cells that require different determined stem cells placed in different body regions. Consequently, the dedifferentiation process, necessary for Amphibia regeneration, is not necessary for organisms like planarians which are in a continuous state of rapid cell turnover¹⁰. Unless new data on planarian histology and cytology, cell dynamics, and life cycle are obtained, the extrapolation of other mechanisms of regeneration to planarians^{1,9} and the construction of theoretical models of planarian regeneration¹¹ will be of little value.

J.M.W. Slack comments: In my article I attempted to show that several *independent* issues are involved in establishing the source of cells for regeneration, each of which must be approached through a different experiment. As Baguña implies, the simple dichotomy — 'neoblasts versus metaplasia' — is often not an adequate statement of the problem. I believe that the controversy which has arisen in this field in the past has largely been caused by an imprecision in the question asked. □

A carbohydrate signal for intracellular transit

from Mike Geisow

JUST over a year ago, the function of the oligosaccharide chains added to many newly synthesized proteins was discussed in these columns (*Sugars and intracellular recognition*, *Nature* 281, 15, 1979). It was noted that an early hypothesis — that carbohydrate acted as a marker for secretion — had been superseded by the discovery of the signal peptide. However, it did seem as if carbohydrate on non-secreted proteins might still act as a signal for intracellular transit from the endoplasmic reticulum to subcellular, membrane-enclosed destinations. Recent work has shown that this is indeed the case for lysosomal enzymes.

Characteristically, lysosomal enzymes are glycoproteins and many have been shown to contain mannose residues phosphorylated at carbon-6 in the hexose rings. Both glycosylation and phosphorylation occur in the endoplasmic reticulum and appear to be directed by the sequence and conformation of the polypeptide substrate, not all proteins receive both modifications. The importance of both the

mannose and the phosphate groups in receptor-mediated processes first became apparent when glycoproteins expressing both determinants were shown to be rapidly and specifically endocytosed by fibroblasts. Next, the uptake of a variety of lysosomal hydrolases was found to be subject to competitive inhibition by mannose phosphate. These observations suggested three rival routes for lysosomal enzymes from their sites of synthesis to primary lysosomes. Two of these, involving secretion followed by re-uptake or cycling as receptor complexes via the surface membrane, appear to be of minor importance: receptor-saturating levels of extracellular mannose-6-phosphate do not deplete lysosomal enzyme levels. Fischer and his colleagues (*J. biol. Chem.* 255, 9608, 1980) now present firm evidence for a major intracellular transit system using β -hexosaminidase B in fibroblasts.

It was found that 80 per cent of the mannose-6-phosphate receptors were intracellular and faced the interior of endoplasmic reticulum or lysosomes. The highest specific activity of enzyme-binding receptors was present in these cell fractions. Moreover, the intracellular receptors were combined with endogenous enzymes and presented an occupancy gradient which ran steeply downhill from endoplasmic reticulum to lysosomes. The inference is that proteins which receive phosphorylmannose in the endoplasmic reticulum as a result of as yet unknown conformational signals in the polypeptide, are recognized and transferred to primary lysosomes by an essentially intracellular route.

In the report referred to earlier, attention was drawn to the frequent observation of secretory protein proteolysis in endocrine cells treated with inhibitors of protein glycosylation. In such cells, failure of the glycosylation system presumably produces not only non-glycosylated hormones, but also carbohydrate-free acid hydrolases co-synthesized in the endoplasmic reticulum. What happens to the non-glycosylated lysosomal enzymes? In I-cell disease, defective addition of phosphorylated carbohydrate to the enzymes results in their secretion. Co-packaging of acid hydrolases and normal secretory products in the acid environment of a secretion granule may well explain the observed aberrant proteolysis. This argument leads to an interesting thought — is such proteolytic attack on hormones always abnormal? Some hydrolases appear to be naturally present in secretion granules as opposed to lysosomes. These are the conversion enzymes which give rise to products as diverse as insulin, oxytocin and enkephalins from the original precursors. Do such proteases arrive at their destination in the secretory granule because they normally lack a mannose-6-phosphate-containing oligosaccharide chain? □

Beyond the giga-seal

from Robert McBurney

TWO recent technical developments promise a new era in the examination of the movements of ions across the surface membranes of excitable cells. As well as the achievement of much higher current resolutions it is expected that one technique, using an 'excised patch', will make it possible to monitor changes in membrane properties while being able to directly influence the environment on the inside surface of the cell membrane.

The new techniques stem from the development by Neher and Sakmann (*Nature* **286**, 71, 1980) of a method for the direct measurement of the ionic current flowing through single ion channels in biological membranes. These recordings of picoampere (10^{-12} A) currents are made with a specially constructed glass pipette which seals off a small patch of membrane (about $1\ \mu\text{m}$ in diameter) on the surface of a cell from the rest of the surface membrane. The successful interaction of agonist molecules in the solution inside the pipette with receptor-ion channel complexes on the patch of membrane generates discrete pulses of ionic current which are recorded by a low-noise current-to-voltage converter. The current loop for measurements is from the pipette internal solution through open ion channels in the patch to the cytoplasm, then through 'leakage' channels in the membrane outside the patch to the bulk bathing solution and through the recording device to the pipette solution.

If some of the current flowing through the ion channels fails to complete this recording circuit, and a proportion returns via the seal between the pipette wall and membrane or through leakage channels in the patch itself, the true single-channel current amplitude is not measured. While the latter return pathway is not significant, except for larger patches on very small cells, the achievement of adequate seals has been a key factor in the application of this technique to different preparations. Not only does the relationship between seal resistance (R_{seal}) and recording system resistance determine the proportion of the actual current recorded but the thermal current noise in the seal resistance (inversely proportional to $\sqrt{R_{\text{seal}}}$) determines the lower limit of current resolution of the recording system.

Despite problems in creating adequate seals, the patch recording technique has been successfully applied over the past five years to a variety of preparations, including denervated frog muscle, cultured rat muscle (myoballs), locust muscle and

squid giant axons. The channels investigated have mostly been those activated by receptor agonists (cholinergic in frog and rat muscle, glutaminergic in locust muscle), although in one case (squid giant axon) the properties of voltage-dependent K^+ channels have been studied. The technique has been used to confirm and extend data obtained by the analysis of membrane current fluctuations (see Stevens *Nature* **270**, 391, 1977). In addition, it has yielded new information concerning the detailed kinetics of action of some drugs, for example local anaesthetics on acetylcholine-activated ion channels (Neher and Steinbach *J Physiol, Lond* **277**, 153, 1978), and has revealed the behaviour of ion channels during desensitization (Sakmann *et al Nature* **286**, 71, 1980).

The first exciting new development to come from Neher and Sakmann's technique arose from efforts to increase the sealing resistance. By applying suction to the recording pipette as it was placed on the surface membrane of a cultured muscle cell, F Sigworth and E Neher (Göttingen) found that a very high-resistance seal ($>10^9\ \Omega$) was, in some cases, suddenly created. This seal and its associated low current-noise even at a bandwidth from DC-7 kHz allowed Sigworth and Neher to resolve single voltage-dependent Na^+ channels: those normally associated with the generation of muscle action potentials. In their preliminary report (*Nature* **187**, 447, 1980), as well as describing the 'giga-seal' and presenting clear records of single Na^+ channels, they have shown that these channels have conductance and average lifetime values which agree with those obtained by more indirect means. They also demonstrate the independence of channel behaviour by showing that the sum of many records, usually containing just one channel opening in response to a fixed membrane depolarization, mimics the behaviour of many channels operating simultaneously.

The future application of the 'giga-seal' technique to excitable tissues will permit the investigation of 'gated' ion channels in cells or regions of cells not amenable to voltage-clamp analysis with intracellular microelectrodes, such as smooth cells, gland cells, unmyelinated axons and possibly even nerve terminals. In addition, the technique provides improved current resolution and, for single-channel currents already observed by the original method, a much wider bandwidth for recording which will undoubtedly reveal finer details in the kinetics of channel activation and inactivation.

Perhaps more exciting than the achievement of the 'giga-seal' itself has

been the recent observation made by two groups of workers, R Horn and J Patlak (Yale) and O Hamill and B Sakmann (Göttingen). They found that, once established, this seal was almost impossible to shake off. When the electrode was pulled away from the cell it seemed that the patch of membrane was excised on, or within, the tip of the electrode and single-channel currents could still be observed if the transmembrane voltage was appropriately adjusted. After a short time the recording ceased, possibly due to a membrane-bound vesicle being formed within the electrode tip (because the high-resistance seal remained). The two groups solved the problem of vesicle formation in different ways. Horn and Patlak (*Proc natn Acad Sci USA* **77**, 6930, 1980) found that fluoride ions delayed or prevented the process, while Hamill and Sakmann (*J Physiol, Lond* in the press) found that by lifting the electrode through an air-water interface they were able to re-expose the patch.

In their preliminary report Horn and Patlak illustrate one of the special features of this preparation: they examine the dependence of the conductance of acetylcholine-activated channels on sodium ion concentration in a situation where the latter could be defined on both sides of the membrane. Such access permits a vast array of experiments to be undertaken with controlled environments on either side of the membrane, similar in principle to the study of ion transport in 'doped' artificial lipid membranes, and these will certainly result in a clearer idea of the mechanism of ion transport and selectivity of natural ionophores.

However, the most important aspect of the preparation may simply prove to be access to the inside surface of cell membranes. It will now be possible to investigate directly the action of intracellular messengers (for example, cyclic nucleotides, Ca^{2+}) and cellular metabolic products on membrane excitability and transport processes. It is hoped that this 'excised patch' technique will be generally applicable to cells derived from a wide range of tissues. For example, its application to heart cells will certainly provide an excellent preparation with which to study the relationships between 'second messengers', and protein phosphorylation and ion channels in the hormonal modulation of membrane conductance changes underlying cardiac pacemaker activity. □

Erratum In *Antimatter back to front* by C H Llewellyn Smith (*Nature* **289**, 534 February 12, 1981) the last sentence in the first paragraph should have read "The discovery of CP violation by Christenson, Cronin, Fitch and Turlay in 1964, for which Cronin and Fitch were awarded the 1980 Nobel prize, was therefore almost as great a shock as the discovery of parity violation".

Corrigendum. In *Cement — a respectable material?* by D D Double (**289**, 348, January 29, 1981) the figure of "100 MN m⁻²" quoted as the modulus of mother-of-pearl shell should have been "about 60 GN m⁻²".

Mesoscale convection in the clouds of Venus

C. C. Covey & G. Schubert

Department of Earth and Space Sciences, University of California, Los Angeles, California 90024, USA

The cellular structures seen in UV images of the atmosphere of Venus probably represent convection cells. If so, this shape (horizontal dimensions 10–100 times greater than vertical dimensions) cannot be accounted for by radiation transfer alone but requires anisotropic eddy diffusivity

UV PICTURES of Venus taken by the Mariner 10 and Pioneer Venus spacecraft show cellular structures near and downwind of the subsolar point at cloud top heights of 60–70 km (Fig. 1)^{1–3}. These structures may result from various eddy phenomena, for example, wave trains intersecting to form a criss-cross pattern. However, the most natural interpretation, given their proximity to the subsolar point, is that they are atmospheric convection cells visible at the cloud tops.

Cloud level convection

The presence or absence of an adiabatic layer at the cloud tops would be strong evidence either for or against convection in this region of the atmosphere. Unfortunately, the four Pioneer Venus probes entered the atmosphere away from the subsolar point, at night or in the early morning. They, nevertheless, all measured an adiabatic temperature gradient between ~50 and 55 km altitude with stable layers above and below⁴. We therefore regard the UV cellular features as evidence for convection in the cloud-top subsolar region and suggest that the cloud level adiabatic layer in this region is either higher or thicker than the one measured by the probes, so as to encompass the cloud tops⁵. For example, in the 55–60 km altitude range the static stability measured by the probes has a mean value of 2–3 K km⁻¹. This 5-km thick layer of the atmosphere could become adiabatic if the temperature were increased by 10–15 K between morning and afternoon. Then the adiabatic layer would extend to 60 km, the lower limit for the altitude of the UV features. The required heating is compatible with a diurnal temperature cycle involving an atmospheric superrotation rate of 5 days⁶ and a radiative cooling time of ~100 days⁷, which represents a temperature variation of ~5%. Alternatively the cellular features may be located in an adiabatic layer above 65 km altitude (where static stability data do not exist)⁵. We might also be seeing penetration of lower lying convection into an overlying stable cloud top region².

An adiabatic cloud top layer is likely to be bounded above and below by regions of high static stability caused by radiative cooling of the cloud tops and radiative heating of the cloud base⁸. The depth of the convecting layer is then of the order of 10 km. Given the horizontal scale of the cellular UV features, 10²–10³ km, this implies aspect ratios (diameter/depth) of the order of 10–10². This is several times the aspect ratio of mesoscale cellular atmospheric convection on Earth⁹, which in turn is several times the aspect ratio obtained in laboratory and theoretical studies of cellular convection at moderately supercritical Rayleigh numbers¹⁰.

We now present a theory to explain these high aspect ratios for cloud level convection in the Venus atmosphere. Mesoscale atmospheric convection on Earth takes place immediately above the planetary surface and it is, therefore, affected by the

very steep temperature gradient in the thermal boundary layer¹¹. The properties of the cloud level Venus atmosphere together with the large aspect ratio of the cells require that the thermal diffusivity due to small-scale eddies be large and anisotropic.

Radiative and eddy processes

The major difference between laboratory and atmospheric convection is that in the latter radiative and eddy processes play a major part in the transport of heat and momentum. To represent the role of eddies an eddy viscosity ν and an eddy thermal diffusivity κ are used. These eddy diffusivities may be anisotropic. To account for this, we let ν and κ represent the diffusivities in the vertical direction and $m\nu$ and $m\kappa$ the horizontal diffusivities. Thus we assume that m , the ratio of horizontal to vertical diffusivity, is the same for momentum and heat transport. To account for radiative heat transfer within the convecting fluid, we linearize the Boussinesq equations for a compressible atmosphere with an internal heat source¹². Q about a basic state in radiative equilibrium. The incremental

Fig. 1 UV image of Venus from the Pioneer Venus Orbiter Cloud Photopolarimeter². The rotation of the atmosphere is from right to left. Cellular structures may be seen in the equatorial region, near and downwind of the subsolar point.

Fig. 2 Critical values of the Rayleigh number for the onset of convection as a function of aspect ratio, for different values of eddy anisotropy ratio m . For these curves $\tau = 10$ and $\gamma = 1$, as implied by $\kappa = 10^6 \text{ cm}^2 \text{ s}^{-1}$.

heating in the perturbed state Q' is approximated by the newtonian cooling law

$$Q'/\rho c \approx -\theta^*/\tau^* \quad (1)$$

where ρ is the density, c is the specific heat at constant pressure, θ^* is the perturbation temperature, and τ^* is the radiative cooling time. The newtonian cooling approximation is valid at cloud levels in the Venus atmosphere, and values of τ^* have been obtained⁷ at different altitudes from detailed radiative transfer calculations.

For simplicity we assume that the thermal expansion coefficient α , the basic state temperature gradient dT_0/dz^* (z^* is altitude), and the adiabatic temperature gradient Γ_{ad} are all constant. Then the governing equations for θ^* , perturbation velocity $\mathbf{u}^*$, and perturbation pressure π^* are

$$\left(\frac{\partial}{\partial t^*} - m\nu\Delta_2^* - \nu\frac{\partial^2}{\partial z^{*2}}\right)\mathbf{u}^* = -\nabla^*\pi^* + g\alpha\theta^*\mathbf{k} \quad (2)$$

$$\nabla^*\mathbf{u}^* = 0 \quad (3)$$

$$\left(\frac{\partial}{\partial t^*} + \frac{1}{\tau^*} - m\kappa\Delta_2^* - \kappa\frac{\partial^2}{\partial z^{*2}}\right)\theta^* = \left(\left|\frac{dT_0}{dz^*}\right| - \Gamma_{ad}\right)(\mathbf{k} \cdot \mathbf{u}^*) \quad (4)$$

In the above, $-g\mathbf{k}$ is the acceleration of gravity and Δ_2^* is the laplacian with respect to horizontal coordinates. We have assumed a motionless basic state and have thus neglected any wind velocity gradients. The zonal wind at the cloud tops is large but its vertical shear is unknown⁵. The fact that the putative convective features are cells instead of rolls argues that the wind shear is small enough to be neglected³.

We remove dimensions from equations (2)–(4) using the depth of the fluid d as the length scale, d^2/κ as the time scale, and $(|dT_0/dz^*| - \Gamma_{ad})d$ as the temperature scale. This gives

$$\left(\frac{1}{P}\frac{\partial}{\partial t} - m\Delta_2 - \frac{\partial^2}{\partial z^2}\right)\mathbf{u} = -\nabla\pi + R\theta\mathbf{k} \quad (5)$$

$$\nabla \cdot \mathbf{u} = 0 \quad (6)$$

$$\left(\frac{\partial}{\partial t} + \frac{1}{\tau} - m\Delta_2 - \frac{\partial^2}{\partial z^2}\right)\theta = \mathbf{k} \cdot \mathbf{u} \quad (7)$$

where $\mathbf{u}$, π , θ , t , z , ∇ , and Δ_2 are dimensionless quantities and operators. Physical processes within the fluid are then determined by four nondimensional parameters: m , the Prandtl number

$$P \equiv \nu/\kappa \quad (8)$$

the Rayleigh number

$$R \equiv \frac{\alpha g(|dT_0/dz^*| - |\Gamma_{ad}|)d^4}{\nu\kappa} \quad (9)$$

and the dimensionless radiative cooling time

$$\tau = \tau^*\kappa/d^2 \quad (10)$$

We must also account for the effect of radiative transfer at the boundaries of the convecting fluid. At the upper boundary, the additional heat conducted upwards in the fluid $-\rho\kappa d\theta^*/dz$ must equal the extra heat radiated to space $4\sigma T_0^3\theta^*$. A similar condition applies at the lower boundary. Thus, in nondimensional form,

$$\frac{d\theta}{dz} \pm \gamma\theta = 0 \quad \text{at } z = \pm \frac{1}{2} \quad (11)$$

where

$$\gamma \equiv \frac{4\sigma T_0^3 d}{\rho\kappa} \quad (12)$$

We assume free boundaries as appropriate for a convecting layer within an atmosphere. The velocity boundary conditions are¹⁰

$$\mathbf{u} \cdot \mathbf{k} = \frac{d^2}{dz^2}(\mathbf{u} \cdot \mathbf{k}) = 0 \quad \text{at } z = \pm \frac{1}{2} \quad (13)$$

Two special cases illustrate the different roles of radiative transfer within the fluid and at the boundaries. In the limit $\gamma \rightarrow \infty$, equation (11) becomes the isothermal condition $\theta = 0$ commonly used in convection theory. This case of perfectly conducting boundaries neglects the role of radiation in exchanging heat at the boundaries. The effect of the τ^{-1} term, which represents radiative transfer within the fluid, is then to increase the stability of the fluid and to decrease the aspect ratio of convection cells. This result was also obtained by Goody¹³, who incorporated the equations of radiative transfer into the formulation of the convection problem but used the boundary condition $\theta = 0$. The stabilizing effect occurs because radiative

Fig. 3 Aspect ratio for the minimum Rayleigh number, as a function of κ , for various values of m .

Fig. 4 Minimum convective heat flux required to sustain convection for the indicated values of κ and m

transfer adds to the effect of conduction in equalizing temperature differences between different parts of the fluid. The decrease in aspect ratio occurs because radiative transfer, unlike conduction, does not depend on the proximity of hot and cold fluid elements. In ordinary convection problems, cells with low aspect ratios are not seen because the proximity of hot upwelling regions and cold downwelling regions leads to large horizontal conductive heat transfer. When radiative transfer carries a significant amount of heat, this effect becomes less important and the cells tend to have lower aspect ratios.

The limit $\tau \rightarrow \infty$ accounts for radiative transfer at the boundaries but not within the bulk of the convecting fluid. As γ decreases the fluid becomes less stable and the aspect ratio of convection cells increases^{11,14,15}. The smaller γ is, the less efficient is radiation in exchanging heat at the boundaries. This explains the decreased stability of the radiative-convective static state. Fluid parcels must also spend more time at the boundaries exchanging heat, and this results in larger aspect ratios.

Thus, radiative transfer at the boundaries and within the fluid have opposite effects on the aspect ratio. In addition, anisotropic diffusivities with $m > 1$ tend to increase the aspect ratio^{16,17}. To see which effect 'wins' we solve the boundary value problem for realistic parameter values. Except for the eddy diffusivities, these are known at least in order of magnitude: $d \sim 10$ km, at 60 km altitude $c = 8.6 \times 10^6$ erg g⁻¹ K⁻¹, $\rho = 0.5 \times 10^{-3}$ g cm⁻³, and $T_0 = 270$ K from *in situ* probe measurements⁴, at cloud levels $\tau^* \sim 10^7$ s according to radiative transfer calculations⁷. Using these values, equations (10) and (12) give

$$\tau = \kappa / (10^5 \text{ cm}^2 \text{ s}^{-1}) \quad (14)$$

$$\gamma = (10^6 \text{ cm}^2 \text{ s}^{-1}) / \kappa \quad (15)$$

Thus, choosing the vertical thermal diffusivity κ determines τ and γ . The boundary value problem can then be solved by standard methods¹⁰. The onset of convection is steady for finite γ (ref. 11) and the additional effects of finite τ and $m \neq 1$ should not change this result. Thus we set $\partial/\partial t = 0$ in equations (5)–(7). We assume a horizontal wavenumber a and obtain an eigenvalue problem that determines R , the Rayleigh number for the onset of convection, as a function of a .

Figure 2 shows R plotted against the aspect ratio ($2\pi/q$) for different values of m , obtained by numerical solution of the eigenvalue problem with $\kappa = 10^6 \text{ cm}^2 \text{ s}^{-1}$. To match the cell dimensions observed in the Venus atmosphere, the minimum R must occur for aspect ratios of 10–100. Figure 2 shows that this occurs for $\kappa \sim 10^6 \text{ cm}^2 \text{ s}^{-1}$ and $m \sim 100$. These are magnitudes commonly used for the terrestrial atmosphere^{16–18}. Thus our theory can explain the high aspect ratios using reasonable parameter values.

There are, of course, many combinations of κ and m which give the desired aspect ratios. Figure 3 plots the aspect ratio at minimum R as a function of κ . There is a trade-off between m and κ : a lower eddy anisotropy is allowed if the magnitude of the eddy diffusivity is larger. For example, $m \sim 10$ and $\kappa \sim 10^7 \text{ cm}^2 \text{ s}^{-1}$ will also give aspect ratios in the range 10–100. Figure 3 also shows the influence of radiative transfer on the aspect ratio. For $\kappa \leq 10^5 \text{ cm}^2 \text{ s}^{-1}$ the aspect ratios approach the values one would obtain by neglecting radiative transfer ($\gamma = \tau = \infty$). For larger values of κ there is a noticeable effect: the boundary radiation effect (γ) dominates the internal radiation effect (τ), so that the aspect ratio is increased. Larger values of κ imply that eddies transfer heat very efficiently within the fluid. At the boundaries, heat is transferred by radiation because eddies are suppressed in the stable layers which bound the convecting region. This radiative transport is comparatively inefficient, causing larger aspect ratios as explained above.

The heat transport due to convection provides an important constraint on the size of κ . For instance, using $\kappa = 10^6 \text{ cm}^2 \text{ s}^{-1}$ and $m = 100$ we find a minimum Rayleigh number of 2.27×10^4 (Fig. 2). Using $\nu = \kappa$ we find

$$|dT_0/dz^*| - \Gamma_{ad} = \nu \kappa R / \alpha g d^4 = 7 \times 10^{-4} \text{ K km}^{-1} \quad (16)$$

This is the minimum superadiabaticity required to sustain convection in this case. It implies a minimum convective heat flux

$$\rho c \kappa (|dT_0/dz^*| - \Gamma_{ad}) = 6 \times 10^{-2} \text{ W m}^{-2} \quad (17)$$

Increasing κ will rapidly increase the heat flux to values greater than the downward solar radiative flux at cloud levels (estimated at 10^2 W m^{-2} from Pioneer Venus probe data¹⁹), a non-physical result. Figure 4, displaying the results of calculations analogous to equations (16) and (17) for different m and κ , shows that this limit is reached for $\kappa \geq 10^8$ when $m = 1$. Thus the combination $m = 1$, $\kappa \geq 10^8$ is ruled out even though it provides the correct aspect ratios (Fig. 3).

Conclusions

Our results show that the apparent flatness of large-scale convection cells in the Venus clouds can be explained by anisotropic eddy diffusion and radiative transfer effects. Horizontal eddy diffusivities must be at least 10-fold greater than vertical diffusivities. Anisotropy ratios $\geq 1,000$ are sufficient to account for the flattening in cases where the vertical eddy diffusivity is $\geq 10^5 \text{ cm}^2 \text{ s}^{-1}$ and the effects of radiative transfer are negligible. For vertical diffusivity $\geq 10^5 \text{ cm}^2 \text{ s}^{-1}$ radiative transfer contributes to the flattening. But radiative transfer alone cannot account for the apparent aspect ratios, this would require vertical heat diffusivities large enough to give a non-physically high value of convective heat transport.

The present theory is greatly simplified by the linearization of the equations about a static basic state. We have not only assumed small velocity perturbations but we have also made the Boussinesq approximation, which assumes small density variations. The latter is strictly valid only when the depth of the convecting layer is smaller than a scale height¹² (6 km in the region of interest). Finally, we have accounted for radiative heating within the convecting layer and have found that this effect tends to reduce the aspect ratio of the cells. Yet we cannot rule out the possibility that in fully developed convection the opposite effect occurs. In fact, Tritton has proposed on the basis of laboratory studies that internal heating contributes to the flattening of the convection cells on Venus²⁰. Considerations

such as this underscore the importance of studying nonlinear effects

The structure of eight distinct cloned human leukocyte interferon cDNAs

David V. Goeddel, David W. Leung, Thomas J. Dull, Mitchell Gross, Richard M. Lawn, Russell McCandliss*, Peter H. Seeburg, Axel Ullrich, Elizabeth Yelverton & Patrick W. Gray

Department of Molecular Biology, Genentech, Inc., 460 Point San Bruno Boulevard, South San Francisco, California 94080, USA

* Roche Institute of Molecular Biology, Nutley, New Jersey 07110, USA

Eight classes of human leukocyte interferon (LeIFN) cDNA clones have been identified in a cDNA library prepared from a myeloblastoid cell line. The nucleotide sequences demonstrate that the multiple human LeIFN genes code for a family of homologous, yet distinct proteins. One of the cDNA clones may have been derived from the transcription of a LeIFN pseudogene.

INTERFERONS are a family of proteins which confer viral resistance in target cells^{1,2} as well as inhibiting cell proliferation and modulating immune response (see refs 2, 3 for reviews). Human interferons were originally classified by their respective cells of origin. The major interferons produced in leukocytes (LeIFN or IFN- α) and in fibroblasts (FIFN or IFN- β) have been shown to be antigenically distinct, acid-stable molecules collectively designated 'classical' or type I interferons. Intense clinical interest in IFN coupled with the inability to obtain large amounts of the purified protein from human cells has spurred efforts to produce high yields of human interferon in the bacterium *Escherichia coli* by recombinant DNA procedures. Several groups have recently reported the bacterial synthesis of various interferons⁴⁻⁹, and the efficacy of such material in limited animal testing has been demonstrated⁵.

We recently described the construction of a collection of cDNA clones prepared using 12S RNA isolated from a human myeloblastoid cell line⁵. Several cDNA clones were identified by hybridization with synthetic DNA probes designed from partial amino acid sequence information of human leukocyte interferon. The cDNA insert of one of the hybrid plasmids (pL31) was sequenced and used to construct a plasmid which directed the synthesis of large amounts of a biologically active human LeIFN, termed LeIFN A (ref 5). Restriction endonuclease analysis showed extensive differences between the additional hybridizing clones, suggesting that several different human LeIFNs might be expressed by the myeloblastoid cell line KG-1 (ref 10). Furthermore, pL31 differs considerably from the human LeIFN cDNA clone described by Weissmann and colleagues⁴ in both nucleotide sequence and deduced amino acid sequence, yet both of the encoded LeIFNs show antiviral activity^{4,5}.

Additional evidence for the existence of a multigene family of human LeIFNs is found in the heterogeneity of the IFN proteins prepared from human leukocytes¹¹ and lymphoblasts^{12,13}. NH₂-terminal amino acid sequences¹²⁻¹⁴ and amino acid sequences of tryptic and chymotryptic peptides¹³ have revealed at least five

distinct, but homologous, LeIFNs. At least eight distinct chromosomal LeIFN genes have recently been isolated from a human gene library (ref 15, and R L and A U, unpublished results). In contrast, there is no evidence for multiple human FIFN genes. NH₂-terminal amino acid sequences of FIFN determined by two different groups^{16,17} agree with results obtained from nucleotide sequencing of cloned FIFN cDNAs^{7,18,19} and FIFN mRNA^{20,21} in suggesting that there may be only one gene for FIFN. We describe here genomic hybridization data consistent with the existence of about ten human LeIFN genes and a single FIFN gene, and present the DNA sequences of eight distinct LeIFN cDNA clones identified in a cDNA library prepared from the myeloblastoid cell line KG-1.

Evidence for multiple LeIFN genes

To estimate the number of LeIFN genes in the human genome, human spleen DNA was digested with various restriction endonucleases, electrophoresed through agarose gels and transferred to nitrocellulose paper²². Hybridizations were done using radiolabelled LeIFN and FIFN⁷ cloned cDNAs (Fig 1). The number of LeIFN genes can be estimated from the number of hybridizing bands in the lanes containing *Hind*III and *Taq*I digests. As none of the LeIFN cloned cDNAs contains either of these restriction sites (see below), and because the human LeIFN genes do not seem to have any intervening sequences (ref 15, and R L and A U, unpublished results), it is likely that each band corresponds to at least one gene. Therefore, the hybridization patterns suggest the presence of at least ten LeIFN genes and only one FIFN gene. Identical patterns were obtained for the LeIFN genes regardless of whether only LeIFN A cDNA was used as the radiolabelled probe or several different types of LeIFN cDNAs were used as a mixed probe. The fibroblast interferon gene contains an internal *Bgl*II site^{7,18,19}. Only one hybridizing band was obtained for FIFN in the *Bgl*II digest because the hybridization probe was an isolated *Bgl*II-*Pvu*II fragment from cloned FIFN cDNA (ref 7).

Fig. 1 Hybridization of human DNA with interferon cDNA probes. Human spleen DNA was isolated by the procedure of Blin and Stafford⁴³ and digested with the indicated restriction endonucleases. Samples (5 μ g) were electrophoresed in a horizontal 0.8% agarose slab gel and transferred to nitrocellulose filter paper²². Isolated DNA fragments consisting of *a*, a *Bgl*II-*Pvu*II fragment from cloned human IFN cDNA (ref. 7) or *b*, LeIFN A, B, C and E interferon cDNA sequences were ³²P-labelled to a specific activity of $\sim 10^6$ c.p.m. μ g⁻¹ by random calf thymus DNA fragment primed replication⁴⁴. Hybridizations were done using 5×10^6 c.p.m. of probe at 42 °C in 50% formamide, $5 \times$ SSC, $5 \times$ Denhardt's reagent⁴⁵, 50 mM sodium phosphate buffer, pH 6.5, 200 μ g ml⁻¹ denatured salmon sperm DNA and 10% dextran sulphate. After 24 h, the filters were washed at 60 °C in $0.1 \times$ SSC, 0.1% SDS as described elsewhere²⁷. Sizes in kilobase pairs (kb) of bacteriophage λ DNA digested with *Hind*III and included in the gels as size standards are indicated. All the LeIFN cDNAs described in this paper readily cross-hybridize so that hybridization patterns similar to those in *b* have been obtained with single LeIFN cDNA probes. Two additional *Bgl*II fragments of ~ 2.0 and 1.5 kilobase pairs hybridize to LeIFN cDNA probes but are not discernible in this figure.

Identification and classification of multiple LeIFN cDNA clones

To investigate the multiplicity of cloned human LeIFN cDNAs, an *in situ* colony screening procedure²³ was carried out on 4,000 individual colonies of our cDNA library. About 50 clones hybridized to a 260-base pair *Bgl*II fragment from pL31 encoding amino acids 61–150 of LeIFN A. Of these, 33/50 contained cDNA inserts of 700 base pairs or longer and were selected for further analysis. The cDNA inserts were mapped using the restriction enzymes *Pvu*II, *Bgl*II and *Eco*RI, because *Pvu*II and *Bgl*II had been found to cleave LeIFN A cDNA⁵ and

all three cut the LeIFN cDNA cloned by Nagata *et al.*⁴ These restriction endonuclease maps allowed the division of the LeIFN cDNAs into eight groups (A to H, see Fig. 2). The largest cDNA inserts in each group were sequenced by a combination of the Maxam–Gilbert chemical procedure²⁴ and the dideoxy-chain termination procedure using the bacteriophage M13 cloning vector mp7²⁵. It was possible that different LeIFN cDNAs would display the same restriction enzyme map. Because the 3'-noncoding regions of the eight sequenced cDNA clones showed much less homology than their respective coding portions, partial sequencing was done on the 3' regions of several additional cDNAs (five cDNAs each of LeIFN A and LeIFN D, and all the cDNAs in the remaining six groups). This analysis revealed that one of the cDNA clones originally classified as type C was actually a LeIFN H-type cDNA clone which did not extend to the single 5' *Pvu*II site, giving a total of two LeIFN H cDNA clones. However, as discussed in more detail below, the nucleotide sequences of these two LeIFN H cDNA clones differ at three positions.

The restriction enzyme analysis had shown that 14 of the 33 LeIFN cDNA clones were of type LeIFN A and 9 were LeIFN D. No variations in sequence were found among the five LeIFN A cDNAs or the five LeIFN D cDNAs which were partially sequenced—this suggests that the restriction maps are indicative of distinct classes of LeIFNs. LeIFNs A and D were the only groups represented more than twice in the collection of LeIFN cDNA clones. This result was not an artefact due to use of LeIFN A cDNA as the original hybridization probe; no additional LeIFN cDNA clones were found when the 4,000 colonies of the cDNA library were tested again using mixed LeIFN A, B, C, E and F cDNA probes.

The complete sequences of the longest cDNA inserts for each of the eight classes of LeIFN are shown in Fig. 3. Pairwise comparisons of these sequences show that homologies in the coding regions range from 84 (LeIFN B versus LeIFN E) to 94% (LeIFN C versus LeIFN F). The DNA sequences were used to predict the primary protein structure of the different human LeIFNs (Fig. 4). The cDNA clones for LeIFN types A, B, C, D, F and H contain complete coding sequences for the 23-amino acid precursor signal peptide^{4,5} and the 166 amino acids of the mature LeIFNs (165 amino acids for LeIFN A, which has a deletion at position 44). The 5' end of the LeIFN E cDNA begins in the signal peptide region, and also contains an extra base pair at position 187 (Fig. 3). LeIFN G is not a full-length cDNA copy of LeIFN mRNA and contains an incomplete coding sequence.

LeIFN D has the same restriction pattern as the LeIFN cDNA clone described by Nagata *et al.*⁴ The only difference between the two clones in predicted amino acid sequence is at position 114 where valine in LeIFN D replaces alanine²⁶. Weissmann and co-workers⁶ have also recently sequenced a partial-length LeIFN cDNA clone of a second type (which they named α_2) which differs from LeIFN A only at the codon for amino acid 23 (arginine in α_2 , lysine in LeIFN A).

Table 1 Pairwise comparisons of differences in coding sequences of human LeIFNs

	A	B	C	D	E	F	G	H	
A		31 (19)	31 (19)	29 (17)	41 (25)	30 (18)	18* (14)	28 (17)	Mature LeIFNs

H	6 (26)	6 (26)	6 (26)	4 (17)	—	6 (26)	—		
LeIFN signal peptides									

The number of amino acid replacements in each pair of coding sequences are shown. The 23 amino acid signal peptides are compared in the lower left part and the 166 amino acid mature LeIFNs are compared in the upper right part of the table. The total number of differences between pairs is listed first, followed by the percentage difference (numbers in parentheses). Signal sequences for LeIFNs E and G are not known, thus there are no values for comparisons involving either of these sequences.

* Only the 133 C-terminal amino acids of LeIFN G can be deduced from the cDNA sequence, thus in pairwise comparisons involving LeIFN G only differences in these 133 amino acids are considered.

2515 R 416

Fig. 2 Restriction endonuclease maps of the eight types of LeIFN cloned cDNAs (A-H). 33 LeIFN cDNA clones with *PstI* cDNA inserts >700 base pairs were grouped into these eight classes. The hybrid plasmids were constructed by the dC dG tailing method⁵. Therefore, the cDNA inserts could be excised using *PstI*. The lines at the end of each cDNA insert represent the flanking homopolymeric dC dG tails. The positions of *PvuII*, *EcoRI* and *BglII* restriction sites are indicated. Shaded regions indicate the coding sequences of mature LeIFNs, cross-hatched regions indicate signal peptide coding sequences, and the open regions show 3' and 5' noncoding sequences. The numbers at the right are the total number of cDNA clones in each group, with the per cent in each group in parentheses.

A LeIFN pseudogene is transcribed

The coding region of the LeIFN E cDNA clone contains one nucleotide more than the other LeIFN cDNAs (Fig. 3). The predicted amino acid sequence from this nucleotide insertion onwards (amino acid residue 40 in LeIFN E) bears no resemblance to the other LeIFN protein sequences and results in several in-phase termination codons, the first of which would appear at amino acid position 60. Therefore, the amino acid sequence is shown in Fig. 4 as if this insertion had not occurred. Even with this adjustment, termination codons are encountered at positions 102 and 155—thus they are found in all three reading frames. As a cDNA was cloned that contains an additional nucleotide in the coding sequence for a LeIFN, an artefact may have been created during the process of reverse transcription of mRNA and sequence amplification in *E. coli*. However, the presence of the two additional termination codons could imply that LeIFN E is a copy of a pseudogene analogous to the α - and β -globin pseudogenes²⁷⁻²⁹. If so, this is the first reported evidence of a pseudogene being transcribed into RNA. The biological significance of the transcription and possible translation of this pseudogene has not been determined. The fact that only one cDNA clone of a LeIFN pseudogene was obtained in our extensive search for LeIFN cDNA clones suggests that the transcription of such genes may be very rare. This observation is further supported by our recent isolation from a human chromosomal DNA library of an additional LeIFN pseudogene with a DNA sequence distinct from the eight LeIFN cDNA clones described here (unpublished results).

LeIFN signal peptides

The signal sequences of human LeIFNs A, B, C, D, F and H possess features common to all eukaryotic secretory protein signal sequences. Each contains a long stretch of hydrophobic amino acid residues, perhaps important for association with, and traversal of, the rough endoplasmic reticulum membrane. The hydrophobic regions are flanked by charged and more polar amino acid residues. The signal sequences are rich in serine residues proximal to the prepeptide cleavage site, analogous to the signal sequences of rat proalbumin³⁰ and certain mouse

immunoglobulin chains³¹. Within the cell, removal of the signal peptides is presumably achieved by peptide cleavage between glycine and cysteine residues in all of these LeIFNs.

The signal sequences of many different proteins have been determined and compared³². No major sequence homologies have been detected, the most general feature may be a common secondary or tertiary structure (see ref. 33 for review). It is possible that the junction of distinct structural domains within the signal peptide is recognized by a processing enzyme or signal peptidase³⁴, resulting in production of the mature secreted protein and complete translocation into the lumen of the rough endoplasmic reticulum.

The signal sequences of the LeIFNs reported here are only ~70% homologous when compared with each other, except for types C and F, which are identical (Table 1). Only 11 of the 23 amino acids (43%) occur in invariant positions in all six prepeptides. The sequence of the human FIFN signal peptide^{7,18-20} is completely different from those of the human LeIFNs.

Mature leukocyte interferons

The mature LeIFNs are more closely related in their amino acid sequences (~80% homology) than are their corresponding signal peptides (see Table 1). A total of 79 out of 166 amino acids (48%) of the mature polypeptide are identical in all sequences examined (Fig. 4). If the LeIFN E pseudogene amino acid sequence is ignored, then 99 amino acids (60%) occupy identical positions. When the human FIFN sequence^{7,18,19,21} is compared with the LeIFN sequences, only 39 amino acids out of 166 (23%) appear in identical positions (Fig. 4). The overall distribution of amino acid differences along the LeIFN molecules seems to be random, with the possible exception of the region between amino acids 115 and 151. All the LeIFN cDNA clones (again excluding LeIFN E) code for the same amino acid in 31 out of 37 (84%) positions in this region. Residues 116-150 also display the greatest similarity to FIFN (17 out of 35 positions identical), which suggests that this region is of functional importance.

The changes in amino acid sequences between the LeIFNs are largely due to single nucleotide changes, there are several sites (that is, positions 37, 107 and 160) where nonconservative amino acid changes occur. Note that the nucleotide sequence of LeIFN B contains an insertion of a thymidine residue after nucleotide 362 (codon 98), which changes the translational reading frame and results in four distinct codon changes. After position 373 (codon 101) an adenosine residue has been deleted which restores the original reading frame.

	97					102
	Glu	Ala	Cys	Val	Ile	Gln
LeIFN A	GAA	GCC	TGT	GTG	ATA	CAG
	Glu	Val	Leu	Cys	Asp	Gln
LeIFN B	GAA	GTC	CTG	TGT	GAT	CAG

The shorter (~800 base pairs) of the two LeIFN H-type cDNA clones, which we have designated LeIFN H₁, has a deletion (cytidine, nucleotide number 545) which is followed six nucleotides later by a correcting insertion (guanosine, after position 551).

	158				162
	Leu	Gln	Lys	Arg	Leu
LeIFN H	TTG	CAA	AAA	AGA	TTA
	Leu	Lys	Lys	Gly	Leu
LeIFN H ₁	TTG	AAA	AAA	GGA	TTA

Except for this difference and a single base change in the 3' noncoding regions, the nucleotide sequences of LeIFN H and LeIFN H₁ cDNAs are identical. It is possible that these two cDNA clones may represent allelic forms of a single LeIFN gene found in the KG-1 cell line.

The location of cysteine residues is often highly conserved in proteins. All the LeIFNs sequence code for cysteines at positions 1 and 139 of the mature protein. All predicted LeIFNs

Fig. 3 Nucleotide sequences of the eight LeIFN cDNAs (A-H) DNA sequences of the *Pst*I inserts shown in Fig 2 were determined by the Maxam-Gilbert technique²⁴ and by the dideoxy chain termination procedure after subcloning into the M13 vector mp7 (ref 25). The ATG translational initiation codon and the termination triplet for each LeIFN are underlined. The gaps at position 187 were introduced to maximize homologies in the coding regions.

Fig. 4 Comparison of the eight LeIFN protein sequences (A-H) predicted from nucleotide sequences. The one-letter abbreviations recommended by the IUPAC-IUB Commission on Biochemical Nomenclature⁴⁶ are used. A, alanine, C, cysteine, D, aspartic acid, E, glutamic acid, F, phenylalanine, G, glycine, H, histidine, I, isoleucine, K, lysine, L, leucine, M, methionine, N, asparagine, P, proline, Q, glutamine, R, arginine, S, serine, T, threonine, V, valine, W, tryptophan, and Y, tyrosine. The numbers refer to amino acid position (S refers to signal peptide). The dash in the 165 amino acid LeIFN A sequence at position 44 is introduced to align the LeIFN A sequence with the 166 amino acid sequences of the other LeIFNs. The LeIFN E sequence was determined by ignoring the extra nucleotide (position 187 of Fig. 3) in its coding region. Asterisks indicate in-phase termination codons. Amino acids common to all LeIFNs (excluding the pseudogene LeIFN E) are also shown. The underlined residues are amino acids which are also present in human IFN^{7,18,19,21}.

except LeIFN E contain a cysteine at position 29, and all except LeIFN B (Cys 100) contain a cysteine at position 99. At least one intramolecular disulphide bridge has been predicted on the basis of loss of interferon activity on incubation with reducing agents³⁵. Allen and Fantes¹³ have shown that the N-terminal cysteine is probably involved in a disulphide bond. Furthermore, the presence of two disulphide bridges in the LeIFN A produced in *E. coli*⁵ has been established by analysis of tryptic digests of the purified protein. Cys 1 is bonded to Cys 99 and Cys 29 is bonded to Cys 139 (ref. 47). The fact that cysteine residues are also predicted in human IFN^{7,18,19,21} in the positions corresponding to amino acids 29 and 139 of LeIFN suggests that this disulphide bond also occurs in IFN.

NH₂-terminal sequences of human LeIFN species isolated from lymphoblasts^{12,13} and leukocytes¹⁴ have been determined by protein microsequence analysis. The sequences determined by Zoon *et al.*¹² and Levy *et al.*¹⁴ both have NH₂-terminal serine residues. The sequences published by Allen and Fantes¹³ begin with cysteine residues. The seven full-length LeIFN cDNAs (A-F, H) all code for mature LeIFNs beginning with cysteine. Although it is possible that a LeIFN cDNA clone will be identified which encodes an N-terminal serine, it is more likely that the determination of serine arose artefactually through oxidation of cysteine during the initial protein microsequencing procedure.

Disregarding the discrepancies at amino acid position 1, the following comparisons can be made. The 32 NH₂-terminal amino acids of the lymphoblastoid IFN sequence of Zoon *et al.*¹² have the greatest homology with LeIFN F, with only position 26 (Pro in LeIFN F, Leu in lymphoblastoid IFN) differing between the two species. The 22 NH₂-terminal amino acids of LeIFN determined by Levy *et al.*¹⁴ show the most homology with LeIFN A. These differ only at position 11 (Asn in the Levy sequence compared with Ser for LeIFN A). Allen and Fantes¹³ have determined the sequences of tryptic and chymotryptic peptides of two forms of LeIFN: IFN- α A and IFN- α B¹³. IFN- α A comprises at least two different polypeptides of 165 amino acids with the same amino acid deletion at position 44 that is predicted by the LeIFN A cDNA sequence. 140 of the 142 amino acids which have been determined from the IFN- α A peptides correspond to the LeIFN A cDNA sequence presented

here, only Asp 84 and Pro 88 of IFN- α A are not predicted by the LeIFN A cDNA sequence. IFN- α B consists of at least three polypeptides of 166 amino acids each and the residues present at 161 positions have been determined¹³. Peptides of IFN- α B are most closely related to LeIFN D, with only Met 60, Thr 64 and Ala 114 not being predicted by the LeIFN D cDNA sequence. The 77 N-terminal amino acids of LeIFN F are found in the IFN- α B peptide sequences. However, there are 11 differences between these two interferon sequences in the C-terminal portion (residues 78-166) of the polypeptides. Amino acid sequences deduced from LeIFN B, C, G and H cDNAs do not seem to be represented in either IFN- α A or IFN- α B peptide sequences. These comparisons suggest the presence of additional LeIFN genes, cDNA copies of which are not present, or have not been identified, in our cDNA library. Whether some of the slight differences between LeIFN sequences described above could be due to allelic variation in the human population awaits a detailed genomic characterization of the LeIFN gene family from an individual.

Noncoding sequences of LeIFN

A limited amount of sequence information is available for the 5' noncoding regions of the LeIFN cDNAs (Fig. 3). Obvious homologies exist in the regions immediately preceding the translational initiation codon, LeIFNs A, B and D are similar in this region, as are LeIFNs C and F.

The 3' noncoding regions of the LeIFN cDNA clones vary in size from 242 (LeIFN D) to 441 (LeIFN B) base pairs, counting from the first nucleotide of the stop codon to the site of polyadenylation. Figure 5 shows an alignment of these sequences with gaps introduced to achieve maximum homology. These gaps may be sites of deletions or insertions occurring during the evolution of this multigene family³⁶. The overall homology between 3' noncoding regions is lower than that within the protein coding regions, although certain portions of the 3' noncoding region are relatively conserved. Both the reduced level of 3' noncoding homology and the substantial deletions in the sequence alignments resemble the situation found when comparing the analogous DNA sequences of members of the human β -like globin gene family³⁶. Such results suggest that the precise sequence of much of the 3' noncoding regions of

eukaryotic mRNAs is not essential for function. Experiments involving *in vitro* translation of mRNAs with large 3' deletions support this suggestion^{37,38}.

Efstratiadis *et al.*³⁶ have noted that short (2–8 base pairs) tandem repeats often surround the deletion sites in the β -like globin gene family 3' noncoding sequences. They suggested a mechanism of 'slippage' during DNA replication followed by scission of resulting single-stranded DNA loops as a possible cause of these deletion events during evolution. Such short tandem repeats also occur at many of the deletion points in the LeIFN cDNA sequences.

The hexanucleotide AATAAA precedes the site of polyadenylation in many eukaryotic cellular mRNAs by 15–25 bases³⁹. Although exceptions to the rule have been found in several RNA viruses⁴⁰, this sequence is thought to be involved in mRNA processing and/or polyadenylation. A variant of this sequence, AATTAAA, has recently been reported which precedes the poly(A) site in rat amylase⁴¹ and anglerfish somatostatin⁴² mRNAs. LeIFN A, D, F and G cDNAs contain the hexanucleotide AATAAA ending 20, 21, 14 and 21 nucleotides, respectively, from their polyadenylation sites. LeIFN B, C, E and H cDNAs do not contain this hexanucleotide. At the nucleotide position (nucleotides 347–352, Fig. 5) corresponding to AATAAA in the LeIFN A, D and G cDNAs, the sequence of the other cDNAs differ by one or two nucleotides. This sequence divergence may have led to the extension of the 3' noncoding region in those genes. While LeIFN F mRNA continues until an AATAAA is encountered 14 nucleotides before its poly(A) site, LeIFNs C, E and H possess the related hexanucleotide ATTAATA near their 3' termini (positions 399–404). LeIFN B also has the ATTAATA sequence at this position, but is not polyadenylated until another ATTAATA sequence is reached at positions 484–489. Note that the two cDNA clones most often isolated (LeIFN A and D) have the shortest 3' noncoding sequences and possess the canonical hexanucleotide at the same position.

Fig. 5 Alignment of the 3' noncoding sequences of eight human LeIFN cDNAs. The alignment of sequences between the termination codon and the poly(A) addition site was made using considerations described elsewhere³⁶. Blank areas indicate gaps introduced to achieve consistent alignments. The sequence AATAAA common to most eukaryotic polyadenylated mRNAs³⁹ is underlined. The related sequence ATTAATA, which may also serve as a polyadenylation signal, is indicated by dashed lines.

Significance of the LeIFN multigene family

We have presented here the sequences of eight distinct human LeIFN cDNAs, seven of which probably code for functional interferon polypeptides. LeIFN amino acid sequence information^{12–14} suggests the presence of additional LeIFN structural genes. The genomic blots shown in Fig. 1 and the isolation of chromosomal LeIFN sequences¹⁵ also support the concept of a LeIFN multigene family comprising at least 8–10 distinct human LeIFN-related genes, although some of these could be pseudogenes similar to LeIFN E.

The cDNA clones LeIFN A and D occur relatively frequently in our cDNA library⁵, which was prepared using RNA from the virus-induced myeloblastoid cell line KG-1¹⁰. In contrast, a major LeIFN species found in the lymphoblastoid Namalwa cell line¹² most closely resembles the polypeptide encoded by LeIFN F cDNA—this supports the suggestion of Nagata *et al.*¹⁵ that different cell types might preferentially express different LeIFN genes. Preferential expression of different IFNs might also occur in the same cell line in response to different viruses.

These multiple LeIFNs probably show distinct functional properties. Streuli *et al.*⁶ have shown that two different LeIFNs (IFN- α 1 and IFN- α 2) have striking differences in their antiviral activities on cells of different species. We have recently obtained expression in *E. coli* of the mature LeIFN polypeptides encoded by LeIFN A, B, C, D and F cDNAs (unpublished results) and all five show different cross-species specificities. The availability of these cloned LeIFNs should allow the assignment of the various activities characteristic of mixed leukocyte interferon preparations² to individual LeIFN species. A detailed understanding of the correlation between LeIFN structure and activity may lead to the design of new interferons highly active against particular diseases.

We thank Robert Swanson and Giuseppe Miozzari for their encouragement, and Jeanne Arch, Alane Gray and Suzanne Pfeffer for help in preparing the manuscript. This work was supported by Hoffmann-La Roche Inc. and Genentech Inc.

Homology and concerted evolution at the $\alpha 1$ and $\alpha 2$ loci of human α -globin

Stephen A. Liebhaber, Michel Goossens & Yuet Wai Kan

Howard Hughes Medical Institute Laboratory and Department of Medicine, University of California, San Francisco, California 94143, USA

The identical structure of two racially distinct $\alpha 1$ -globin alleles and the high degree of homology between the $\alpha 1$ - and $\alpha 2$ -globin loci indicate that mechanisms exist for suppression of allelic polymorphisms and for exchange of genetic information within the α -globin gene complex.

THE human α -globin polypeptide chains are encoded at two closely linked loci^{1,2} on chromosome 16 (ref 3). Genomic DNA containing both of these genes has been cloned and mapped⁴. The loci are 3.2 kilobases apart and are oriented in the same transcriptional direction. The more 5' or leftward α -globin gene has been designated as $\alpha 2$ and the more 3' or rightward α -globin gene as $\alpha 1$. The α -globin proteins encoded at these loci have remained identical⁵ even though the duplication of the α -globin gene probably occurred before the mammalian divergence 85 Myr ago and possibly before the bird-mammal divergence a minimum of 300 Myr ago⁶. As gradual accumulation of mutations within these two genes would have caused divergence in the primary structure of the coded proteins over this time period, a mechanism for correcting one gene against another has been postulated⁷. The parallel or coincidental evolution of two genes (concerted evolution⁸) may occur by homologous but unequal cross-over between the two mutually correcting genes. Comparison of α -globin protein structure in primates indicates that this interaction between the two α -globin loci occurs at a high frequency⁶. Comparisons of the structure of the two γ -globin loci (γ^A and γ^G) support the concept of concerted evolution and suggest mechanisms for its implementation^{9,9}. Heteroduplex analysis⁴ and partial sequencing¹⁰ of the DNA within the human α -globin cluster have identified three homologous units that may align the $\alpha 1$ - and $\alpha 2$ -globin genes on sister chromatids, facilitating unequal cross-over between these two loci. To expand on these findings, we have sequenced the $\alpha 1$ -globin genes from two individuals of different races and compared these alleles with each other and with the structure of the $\alpha 2$ -globin gene¹¹. The two $\alpha 1$ -globin alleles are identical, whereas the $\alpha 1$ and $\alpha 2$ loci have diverged in a defined manner. These observations are consistent with frequent exchanges of DNA within the α -globin gene cluster.

Primary structure of two $\alpha 1$ -globin alleles is identical

The $\alpha 1$ -globin genes cloned from the DNA of an Asian (pGL $\alpha 1$) and a Caucasian (pRB $\alpha 1$) were sequenced in parallel. The sequencing scheme used is shown in Fig 1 and the regions

Fig. 1 Strategy for sequencing the $\alpha 1$ -globin genes. Vertical arrows denote restriction enzyme cleavage sites, *AvaI* (Av), *HindIII* (H), *BstE2* (Bs), *PvuII* (Pv). The positions of the capping and poly(A) addition sites as determined from the mRNA^{28,29} are shown. DNA was cut at each of the indicated restriction sites and either 5'-labelled with polynucleotide kinase (BRL) and [γ -³²P]ATP (Amersham, 3,000 Ci mmol⁻¹) after dephosphorylation of the DNA with bacterial alkaline phosphatase (BRL), or 3'-labelled with *Escherichia coli* DNA polymerase I, Klenow fragment (BRL) and the appropriate [α -³²P]dNTP (3,000 Ci mmol⁻¹). These labelled fragments were purified on 5% acrylamide gels and either strand separated³⁰ or secondarily cut by another restriction endonuclease. Gel-purified end-labelled pieces were sequenced by the method of Maxam and Gilbert³⁰. The horizontal arrows are proportional to the distance each fragment was read. All fragments were sequenced twice and in most cases on both strands. bp, Base pairs.

Fig. 2 Sequencing summary. The complete sequence of the $\alpha 2$ -globin allele pSL $\alpha 2$ has been reported¹¹. pGL $\alpha 1$ and $\alpha 2$ are pBR 322 subclones containing respectively the $\alpha 1$ - and $\alpha 2$ -globin genes from a single chromosome (M. Goossens, unpublished data). These were subcloned from a Charon 4A recombinant containing a 14.5-kilobase (kb) *Bam*HI fragment that includes both α -globin genes¹. The DNA originated from the leukocytes of a Chinese subject. pRB $\alpha 1$ and $\alpha 2$ are pBR 322 subclones containing the $\alpha 1$ - and $\alpha 2$ -globin genes from a single chromosome (γ H α G2)⁴ of a Caucasian patient and were provided by T. Maniatis. The plasmid subclones used for sequencing were grown in 15-l batches, amplified at A_{640} 0.7 with chloramphenicol ($150 \mu\text{g ml}^{-1}$), collected 18 h later and purified from a clarified lysate by CsCl isopycnic centrifugation. The extent to which each of these genes was sequenced is indicated by the horizontal arrows (see text for details). The $\alpha 1$ - and $\alpha 2$ alleles were sequenced in parallel to enhance their comparison and to minimize misreadings. Each gene was labelled at the same restriction site, chemical reactions were done simultaneously and, in most instances, the modified and cleaved fragments were electrophoresed side by side on the same gels.

compared in each clone are summarized in Fig. 2. No differences are present in the primary sequence as determined by a direct visual comparison of the adjacent sets of sequencing lanes. Likewise, the sequences of the 230-base pair *Ava*I fragments (Figs 1, 2) encompassing the 5' end of three $\alpha 2$ -globin genes (pSL $\alpha 2$, pGL $\alpha 2$ and pRB $\alpha 2$) are identical and limited sequencing of the 3' end of a fourth $\alpha 2$ -globin allele (Chinese) from the *Bst*E-2 site at AA104 (Fig. 1) to the polyadenylation [poly(A)] site (G. Temple, personal communication) is identical with our reported $\alpha 2$ sequence for a Caucasian (pSL $\alpha 2$)¹¹ (see Fig. 2). This degree of homology was unexpected as Jeffreys has estimated that 1% of the bases in the human β -globin cluster are sites of polymorphism¹². However, this 1% estimate is based on the identification of three restriction site polymorphisms located in the large intervening sequence of the γ and δ genes. Subsequent sequencing of these genes has revealed that an unusually high rate of sequence divergence exists in this region¹³ and that the two polymorphisms noted in the γ -globin genes are probably due to a single initial mutation in one of the γ -globin genes with subsequent transfer of this mutation to the other γ -globin gene⁹. Therefore a reliable overall rate of sequence divergence in the β -globin complex must await comparative sequencing along the entire length of the genes in question.

3' border of homology between the α -globin loci is near the UAA termination codon

Comparison of the α -globin gene sequence at the $\alpha 1$ and $\alpha 2$ loci¹¹ reveals no differences in the 5'-flanking region, the 5'-nontranslated segment, the first exon, or the first intervening sequence (IVS). Exons 2 and 3 each contain one silent third-base substitution. Codon 54 (Gln) is encoded by CAG in $\alpha 1$ and by CAA in $\alpha 2$, and codon 123 (Ala) by GCC in $\alpha 1$ and GCT in $\alpha 2$.

The IVS2 of the $\alpha 1$ -globin gene is nine bases longer and differs by three bases from the same region of the $\alpha 2$ -globin gene (pSL $\alpha 2$). Position 55 of IVS2 is T in $\alpha 2$ -globin and G in $\alpha 1$ -globin. The remaining two base changes and all nine inserted/deleted bases are clustered toward the 3' end of this intron. This finding is consistent with the previous comparison of the pRB $\alpha 1$ and pRB $\alpha 2$ restriction maps which identified a

seven-base insertion/deletion in the same region of IVS2 (ref. 4). Figure 3 shows an alignment of this region that maximizes homology and assumes that the nine bases were deleted as three separate events. The seven-base deletion is flanked by a four-base direct repeat. Deletions in prokaryotic models¹⁴ as well as a number of sequence deletion within the β -globin gene cluster¹³ are similarly flanked by direct repeats in the precursor molecule. Whether the underlined four-base repeat (GGCC, Fig. 3) results in deletion by strand mismatch during DNA replication as suggested by these authors remains speculative, as the current data do not eliminate the possibility that the differences were created by insertions or insertion/deletion combinations.

Heteroduplex mapping studies define several large repeated homologous regions encompassing the $\alpha 1$ - and $\alpha 2$ -globin genes⁴ (Fig. 4a). Proudfoot and Maniatis¹⁰ have sequenced the actual borders of some of these segments. The most leftward homology box begins just 3' to the poly(A) addition site of the pseudo- $\alpha 1$ - and $\alpha 2$ -globin genes. This area includes a large intergenic region of homology between pseudo- α and $\alpha 2$ and $\alpha 2$ and $\alpha 1$ (the X box in ref. 11) (Fig. 4a). Based on the assumption that the 3'-noncoding region of $\alpha 1$ - and $\alpha 2$ -globin mRNA was identical (see below), the poly(A) addition site of these two genes was thought to define the 3' border of a second set of homology regions (the Z box) which encompasses the two α -globin genes and extends 1.5 kilobases in the 5' direction. Our sequence comparison of the 3'-noncoding region of the $\alpha 1$ and $\alpha 2$ genes (Fig. 4b) defines 18 base differences plus a single-base insertion or deletion, making this region only 84% homologous. Thus we would reassign the 3' border of the Z box (the border of α -globin gene recombination—see below) to a position 14 bases 3' to the UAA termination codon. The assumption that the 3'-noncoding regions of both α -globin genes were identical was based on the determination of a unique sequence for this region from reticulocyte mRNA¹⁵. That sequence is almost identical to the gene sequence of the $\alpha 2$ -globin locus, whereas it differs from the $\alpha 1$ -globin gene at 18 bases and one insertion or deletion. Although a definite sequence assignment could not be made at seven positions, only three of these correlate with the base differences between the $\alpha 1$ - and $\alpha 2$ -globin genes. This disparity between the unique sequence of reticulocyte α -globin mRNA and the above genomic sequence data may be reconciled by suggesting that the mRNA transcribed from the $\alpha 2$ -globin locus predominates in circulating reticulocytes due to unequal production or degradation¹⁶.

The sequence divergence between $\alpha 1$ - and $\alpha 2$ -globin genes which begins 3' to the UAA terminator codon and extends into the 3'-flanking region is interrupted by a 50-base pair homologous stretch bridging the poly(A) site and the AAUAAA hexanucleotide (poly(A) signal)¹⁷ (Figs 4b, 5). This region (with the exception of the conserved hexanucleotide AAUAAA) is highly divergent in eukaryotic mRNA in general, and in β -globin can be deleted or inactivated without adversely affecting *in vitro* translational activity¹⁸. Among β -globin and β -like globin genes homology in this region is significant only for the hexanucleotide AAUAAA, its immediately surrounding bases and the sequences adjacent to the poly(A) addition site¹³. Thus the observed maintenance of perfect homology in a segment of

GGC_GCGG_CT_TGGGCC_____GCACT	$\alpha 2$

GGCTGCGGGCCTGGGCCCTCGGCCCACT	$\alpha 1$

Fig. 3 Deletion sites in the 3' end of IVS2. This sequence begins at base 101 of IVS2 and extends through the divergent region to a position 19 base pairs from the junction of IVS2 with exon 3. The sequence of the $\alpha 1$ -globin gene, the $\alpha 2$ -globin gene¹¹ and a possible intermediate sequence are aligned for maximal homology. The open spaces in the $\alpha 2$ -globin gene and the intermediate sequence represent deletions in this region relative to the $\alpha 1$ -globin gene. The dot indicates the position of a base change. The underlined tetranucleotide GGCC is discussed in the text.

Fig. 4 Homologous regions within the segment of α -globin gene cluster containing the $\psi\alpha 1$ -, $\alpha 2$ - and $\alpha 1$ -globin genes. The rectangular blocks represent the respective genes and the open spaces within these blocks represent the introns. Regions that show identity by heteroduplex analysis⁴ or partial sequence determination¹⁰ are given the same letters (X, Y or Z). This figure is adapted from ref. 10 by permission of the author (N. J. P.). **b**, Comparison of the 3' ends of the $\alpha 1$ -globin, $\alpha 2$ -globin and $\psi\alpha 1$ -globin genes¹⁰. The sequence begins at the codon for AA132 of the functional α -globin genes and extends through the TAA ochre codon, the 3'-nontranslated region, and into the 3'-flanking region (lower-case letters). Base differences between the $\alpha 1$ -globin gene and the $\alpha 2$ -globin gene or $\psi\alpha 1$ -globin gene¹⁰ are indicated by the shaded boxes. Deletions are indicated by a hyphen. The region of homology encompassing the $\alpha 1$ - and $\alpha 2$ -globin genes (Z box) has its 3' border approximately 14 bases 3' to the TAA termination codon and the region of homology 3' to the $\psi\alpha 1$ - and $\alpha 2$ -globin genes (X box) has its 5' border six bases 5' to the poly (A) addition site.

this region is probably not entirely explained by functional constraints and could instead be due to a localized transfer of DNA between the two α -globin loci (see below).

Evolution of the α -globin genes

The $\alpha 1$ - and $\alpha 2$ -globin genes may exchange DNA by interaction between malaligned chromosomes. Such interactions may be facilitated by and result in large homologous regions within the α -globin complex (refs 4, 10, see also Fig. 4a). The degree of divergence within these regions would be proportional to the length of time since this exchange occurred. Divergence outside this unit (3'-untranslated and 3'-flanking area of the α -globin genes) might be proportional to some earlier event such as the original α -globin gene reduplication or a subsequent correction. The sequence divergence between the two α -globin genes from the 5'-flanking area to the UAA terminator is 8 bases out of 773 or 1.1% (each postulated insertion or deletion event is given the value of one base change). We assume that the changes within IVS2 are (phenotypically) silent, based on the finding in recently diverged gene pairs that the rate of accumulation of silent changes in coding regions approximately equals that in intervening sequences¹⁹. The 1.1% silent divergence can be equated to divergence time. For recent evolutionary events in the globins (less than 85 Myr) Efstratiadis *et al.*¹³ have calculated a unit evolutionary period (UEP) of approximately 1.3 Myr (1% silent sequence divergence per 1.3 Myr) based on the method of Perler *et al.*¹⁹. Using this constant, the divergence time or time

since the last correction between the $\alpha 1$ - and $\alpha 2$ -globin genes in this homologous region is 1.4 Myr. Similarly, Zimmer *et al.* have calculated that the last correction of the α -globin genes occurred 0.7 Myr ago⁶, based on amino acid differences in several primate species. The divergence in the 3'-noncoding region and 3'-flanking regions is 17.2% (19/110) and 27.8% (17/61), respectively. If the denominators are revised to exclude the 50-base pair homologous region that encompasses the poly(A) addition site, the divergence rates become 29% (19/66) and 42% (17/40) and the estimates of the divergence time become 40.3 and 54.6 Myr, respectively. As duplication of the α -globin gene has been estimated to have occurred before the bird-mammal evolutionary divergence (~300 Myr ago)⁶, the α -globin genes apparently have corrected against each other in the 3'-untranslated and flanking regions at least once and probably numerous times since the original duplication. The observation that the α -globin gene duplication unit contains segments with different levels of homology is not unique as a similar situation has been demonstrated in the γ -globin gene family⁹. It is assumed that the regions with higher homology have undergone more recent genetic exchange.

Evidence cited here and by others^{4,10} supports the concept of recombination and exchange of DNA between defined portions of the two α -globin loci. Mapping of the α -globin genes in patients with α -thalassaemia^{20,21} and confirmatory observations *in vitro* have demonstrated that the α -globin genes can recombine by unequal cross-over at a variety of sites (ref. 4, and

Fig. 5 Distribution of differences in the primary structure of the $\alpha 1$ - and $\alpha 2$ -globin genes. The width of each bar covers a 10-base pair segment and the height is proportional to the number of base differences within that segment. The analysis covers the α -globin genes from 88 base pairs 5' to the cap site and extends through the genes to 61 base pairs 3' to the poly (A) addition site. Each deleted base or group of bases was assigned a value of one base difference (see text).

M Goossens, unpublished data) One outcome of such a strand exchange is a chromosome with three α loci^{22,31} and a chromosome with one α locus²³. Such interactions are made possible by base pairing between two malaligned DNA strands mediated by the repeated homology units encompassing the adjacent loci. The size of these homology units may be determined by the extent of the most recent strand exchange and this in turn would determine the target size and frequency of subsequent interactions. A succession of such strand exchanges of varying lengths would yield adjacent regions that vary in degree of homology. The variation in homology observed on either side of the $\alpha 1$ - and $\alpha 2$ -globin UAA termination codons may be explained by this mechanism. Although a similar mechanism has probably maintained the homology unit common to the two γ -globin genes⁹, this sort of exchange has not occurred at a comparable rate between the closely linked β - and δ -globin genes¹³. The δ -globin gene in all primates studied is either unexpressed or expressed to a very limited extent²⁴. If limited δ -globin gene expression is due to an abnormality in its structure, then an unequal cross-over between the δ -globin and β -globin genes, such as haemoglobin Lepore, might severely diminish the β -globin gene expression leading to a β -thalassaemia phenotype. As it is deleterious, such an exchange would probably be selected against in most populations.

Our comparative sequencing of the $\alpha 1$ -globin genes from an Asian and a Caucasian shows that the sequences of these two $\alpha 1$ alleles are identical. Assuming a UEP of 1.3 Myr (see above) and a target size of 900 base pairs (the region sequenced in both $\alpha 1$ -globin genes), one base difference is expected between the α -globin alleles every 140,000 yr. (This is a minimal estimate because the UEP of 1.3 Myr is for silent changes.) From the

accumulated globin sequencing data available, it seems unlikely that the sequence of each α -globin gene has been so stringently maintained entirely by selective pressure and hence the observed suppression of polymorphism may be the result of a genetic recombination such as that postulated to occur between the γ -globin genes⁹. A mechanism for such structural correction of one allele by another (gene conversion) has been reviewed by Radding²⁵. Homologous interaction between the corresponding loci of two aligned chromosomes which contain distinct alleles can result in a non-reciprocal exchange, with the loss of one allele and its replacement by the other. Such non-reciprocal sister chromatid exchange is observed in yeast²⁶ and *Drosophila*²⁷. As racial divergence probably paralleled population segregation, genetic interaction would not be expected to occur at high frequency across racial lines. Hence the finding of an identical α -globin gene sequence in Asians and Caucasians implies that these two races probably diverged after the establishment in a common precursor population of the most recent conversion at the $\alpha 1$ -globin locus.

Mechanisms of genetic exchange cited above can be constructed to account for the observed patterns of homology within the α -globin gene region. The large repeated regions within this gene cluster probably facilitate such interaction. However, it is unclear whether any selective advantage is gained by maintenance of homology within a duplicated gene locus. How the product of these interactions becomes predominant within a population remains to be defined.

We thank Dr Nancy Cooke for helpful discussions and criticisms of the manuscript, and Kathleen Lee and Kathi A. Begley for technical assistance. This research was supported in part by grants from the March of Dimes/Birth Defects Foundation and the NIH.

Homologous pairing can occur before DNA strand separation in general genetic recombination

Stephen C. West, Era Cassuto & Paul Howard-Flanders

Departments of Molecular Biophysics and Biochemistry, and Therapeutic Radiology, Yale University, PO Box 6666, New Haven, Connecticut 06511, USA

In the presence of ATP and Mg²⁺, purified Escherichia coli recA protein promotes the formation of joint molecules between closed circular duplex DNA and homologous circular single-stranded DNA carrying a short annealed fragment. The presence of this fragment is essential for pairing between molecules. In similar conditions recA protein is unable to act as a helicase and does not cause strand separation of the fragment from the single-stranded circle. Thus, homologous pairing between DNA molecules can take place without prior unwinding of a free end.

A GENETIC approach to the study of general genetic recombination has been to accumulate data derived from meiotic divisions in fungi and to develop models to illustrate how chromosomal DNA molecules might be cut, paired, joined and

matured into recombinant progeny¹⁻⁵. The models proposed by Holliday¹ and more recently by Meselson and Radding⁵ have been used successfully to provide a coherent explanation for extensive data on recombination in fungi^{6,7}—the early steps of

Table 1 Detection of joint molecules by the retention of form I DNA on nitrocellulose filters, after reaction with substrate DNA consisting of Φ X174 viral DNA with annealed fragment

DNA	Proteins	% Duplex DNA retained
(1) Φ X174 substrate + form I Φ X174	—	7.7
Same	recA	19
Same	recA + SSB	37
(2) Φ X174 substrate + form I plasmid	—	7.7
Same	recA	3.0
Same	recA + SSB	5.6
(3) Single-strand Φ X174 + form I Φ X174	—	6.0
Same	recA	6.0
Same	recA + SSB	9.4
(4) Single-strand Φ X174 + form I plasmid	—	10
Same	recA	5.6
Same	recA + SSB	6.5
(5) Form I Φ X174 only	recA + SSB	8.3
Form I plasmid only	recA + SSB	8.0

The assay was essentially that described by Cunningham *et al.*²⁶ Reaction mixtures of 30 μ l contained 20 mM Tris-HCl, pH 7.5, 25 mM MgCl₂, 2 mM dithiothreitol, 100 μ g ml⁻¹ bovine serum albumin, 2 mM ATP, 1.7 nmol substrate or single-stranded Φ X174 DNA, 0.2 nmol ³²P-labelled form I Φ X174 or ³H-labelled form I plasmid pBR322 DNA, 40 μ g recA protein and 2 μ g SSB protein where indicated. After incubation at 37 °C for 30 min, reactions were terminated by the addition of 2 μ l of 0.25 M EDTA and proteins removed from the DNA by the addition of SDS to 1%. Water was added to bring the volume to 200 μ l, and 50 μ l of the reaction mixtures were spotted directly onto nitrocellulose filters (Schleicher and Schuell, BA 85) to measure total counts. The remainder of the reaction mixtures was added to 3 ml of ice-cold 1.5 M NaCl, 0.15 M sodium citrate, pH 7.0, and filtered through nitrocellulose filters. These were then counted for radioactivity and the percentage of joint molecules calculated by determining the percentage of input form I DNA that was retained on the filter due to its hydrogen bonding to substrate DNA. Radioactivity due to the substrate DNA was determined in control experiments and subtracted before calculation of the percentage duplex DNA retained. In experiment 1, the difference of 29% in duplex DNA retained after incubation with recA and SSB proteins was subject to a statistical error of 3.3% (95% confidence limits). The substrate for this assay was prepared by digesting Φ X174 form I ³H-labelled DNA with *Hpa*I restriction enzyme (BRL) and separating the products on a 5% polyacrylamide slab gel. The smallest fragment (392 base pairs) was eluted from the gel, concentrated and denatured by heating, followed by rapid cooling. The fragments were then annealed with the (+) strands of Φ X174 ³²P-labelled DNA. Excess fragments not bound to the (+) strands were removed by neutral sucrose centrifugation. To measure the retention of intact circular DNA on filters that also retain the lightly labelled substrate DNA, highly labelled ³²P form I Φ X174 or ³H form I plasmid pBR322 DNA was used.

the latter model^{5,8} are shown in Fig. 1A. Recombination enzymes from fungi have been studied to a limited extent⁹, however, the cloning of bacterial recombination genes has facilitated the purification of their protein products and opened the way to an enzymological approach to the study of homologous pairing.

In *Escherichia coli*, recombination is controlled by *recA*¹⁰, the structural gene^{11,12} for a single-stranded (ss) DNA-binding protein of 38,000 molecular weight (MW)¹³⁻¹⁸ with ssDNA-dependent ATPase activity^{19,20}. Purified *recA* protein promotes homologous pairing between DNA molecules of various structures. Three situations have been studied: (1) in catalytic amounts, *recA* protein promotes hydrogen bonding between complementary single strands²¹, (2) in stoichiometric amounts, sufficient to cover all the ssDNA present, *recA* protein promotes hydrogen bonding between ssDNA fragments and homologous duplex DNA²²⁻²⁴. The product of the reaction is a D-loop, which contains a heteroduplex region with a single-strand fragment

paired to one strand of the duplex²⁵ (Fig. 1A, III). Pairing may be facilitated as *recA* protein reduces the winding number of duplex DNA²⁴, (3) *recA* protein also promotes homologous pairing between two duplex DNA molecules if one of them contains one or more short single-stranded regions^{26,27}. The latter reaction is of particular interest because genetic recombination in living cells usually involves duplex DNA molecules. Furthermore, because post-replication gaps in UV-ray-irradiated bacteria²⁸ are known to initiate sister exchanges with an efficiency approaching unity²⁹, it is likely that duplex DNA containing single-strand gaps (gapped DNA) is a natural substrate for recombination enzymes.

This important concept is supported by other results obtained with a gapped substrate. In the presence of ATP, *recA* protein recognizes gapped DNA and forms DNA-protein complexes with a high ATPase activity³⁰. If ATP is replaced by the non-hydrolysable analogue γ -S-ATP, this protein binds tightly to duplex DNA containing single-stranded regions, to form thick rod-like structures easily seen by electron microscopy. These rods are visible on gapped but not intact duplex DNA. Because homologous pairing requires ATP hydrolysis^{26,27}, we have suggested that rod-like structures formed transiently in the presence of ATP may participate in pairing between duplex molecules and the recognition of homology³⁰.

Two duplex molecules paired in a region of homology are sometimes referred to as joint molecules. The pairing of gapped DNA with intact homologous duplex DNA by *recA* protein results in joint molecules that are stable when deproteinized by SDS and proteinase K, but unstable in alkali^{26,27}. The paired molecules are linked by noncovalent bonds which show a thermal stability approaching that of duplex DNA²⁶. However, little is known about the structure in the pairing region of these joint molecules. Most published models for genetic recombination between two duplex DNA molecules assume that one duplex is

Fig. 1 Two models for the early steps in general genetic recombination. **A**, The initial steps from the model proposed by Meselson and Radding^{5,8}. I, displacement of a single strand by the replication of remaining strand. The wavy line denotes new synthesis; II, search for homology to single-stranded end; III, uptake of the free end of the displaced strand by a homologous double-stranded molecule to produce a three-stranded structure containing a heteroduplex called a D-loop^{22,25}. **B**, The initial steps of a model involving four-strand homologous pairing before strand separation. I, *recA* protein binds cooperatively to ssDNA at the site of the gap and loads the adjoining duplex; II, the loaded DNA binds nonspecifically and searches for homology in the intact duplex at the expense of ATP. The search may involve one molecule moving over the other or repeated contacts; III, formation of homologous contacts allows hydrogen bonding between the DNA molecules. The site of initial pairing may or may not include the position of the gap. The joint molecules are held by complementary hydrogen bonding, even after the removal of *recA* and SSB proteins. The subsequent steps which, in both models, include cutting, branch migration, isomerization and mismatch correction, are not shown here.

Fig. 2 DNA substrates used in the experiments *a*, Single-stranded Φ X174 viral (+) DNA with a short annealed fragment (—), *b*, the same as *a* but with addition of sonicated (+) DNA fragments, *c*, same as *a* but with intact form I Φ X174 or plasmid pBR322 duplex circular DNA, *d*, single-stranded Φ X174 DNA with intact form I Φ X174 or plasmid duplex circular DNA

cut or gapped, and the single strand with a free end is partially unwound, as shown in Fig 1A, I (ref. 5). The unwound strand is thought to act as a template in the search for complementary sequences in the second duplex. If homologous contacts are made, the free end may wind into the intact molecule to form a heteroduplex, the remaining strand of the second duplex being displaced to form a D-loop (Fig 1A, III).

However, the results of several experiments cannot be easily accounted for by a model for pairing between two duplexes which requires the initial unwinding of a free end: (1) the introduction of interstrand cross-links at both ends of the single-stranded region impairs strand separation but has no effect on the yield of joint molecules²⁷, (2) electron microscopic observations of joint molecules indicate that the joint is often distant from the single-stranded gap²⁶, (3) in addition, the experiments described here show that joint molecules can be formed by recA protein although helicase activity (unwinding and strand separation) could not be detected.

To account for these observations, we present here a working hypothesis for the initial step in homologous pairing between duplex molecules which is an alternative to D-loop formation. Unlike the Meselson–Radding model, it does not require new DNA synthesis and could therefore function in post-replication repair where replication is blocked by damaged bases^{28,29}.

RecA protein does not act as a helicase

Several proteins capable of catalysing the unwinding of duplex molecules have been characterized: helicases I, II, III and rep protein promote the unwinding of partially double-stranded (ds) DNA in ATP-dependent reactions^{31–35}. Incubation of these enzymes with a single-stranded substrate containing a short DNA duplex resulted in the separation of the strands of duplex DNA. This required the presence of single-stranded binding protein (SSB) which bound to the separated single strands and reduced the rate of renaturation³⁶. In addition, exonuclease V unwinds linear duplex molecules in the presence of SSB protein³⁷.

The substrate used in the assay comprised ³²P-labelled complementary strand fragments annealed to ³H-labelled Φ X174 viral (+) strands (Fig 2a). Figure 3 demonstrates that helicase I in the presence of ATP and SSB protein resulted in strand separation, *a* represents the sedimentation at neutral pH of the starting substrate. Although the ³²P-labelled DNA was only 194 nucleotides long, it sedimented rapidly because it was

annealed to the intact Φ X174 DNA. Figure 3b shows the results of incubation of 2 nmol DNA with 1.65 μ g helicase I for 30 min. The reaction mixture was then applied to the top of a neutral sucrose gradient and centrifuged. As can be seen, a portion of the annealed ³²P-DNA (46%) sedimented more slowly, indicating that strand separation had occurred. When SSB protein was omitted (Fig 3c), only a small amount of strand separation (<10%) was observed. Omission of ATP or helicase I gave results identical to those in Fig 3c, that is, no strand separation was observed. Very similar results were obtained when helicase I was replaced by helicase II (data not shown). These results are consistent with published data for helicase-catalysed strand separation^{31,32}.

In parallel experiments using identical conditions, the efficacy of recA protein in the strand separation assay was investigated. Figure 3d shows the results obtained after incubation of 2 nmol of substrate DNA (Fig 2a) with 20 μ g recA protein for 30 min, in the presence of SSB protein, as described above. The ³²P-labelled DNA remained annealed to the intact Φ X174 DNA which indicated that recA protein did not separate the strands. Figure 3e shows the results of a similar reaction from which SSB protein had been omitted. Reactions were also done using recA protein in the range 2–200 μ g, with or without SSB protein or ATP, or where ATP was replaced with 0.5 mM γ -S-ATP, but no strand separation was detected in any of these conditions (data not shown). We also investigated the possibility that homologous ssDNA might stimulate strand separation by recA protein. ³H-labelled Φ X174 (+) ssDNA was sonicated briefly to produce DNA fragments of average length 400 nucleotides, as estimated by sedimentation. Figure 3f shows the results of incubation of 2 nmol of substrate DNA and 4 nmol homologous (+) fragments (Fig 2b) with 40 μ g recA protein and ATP for 30 min as described. Similar results were obtained when the reaction mixture was supplemented with SSB protein (data not shown). No separation of the ³²P-labelled fragment from intact Φ X174 circles by recA protein was observed in conditions in which the separation of 10% of the fragments would have been easily detected.

To determine whether helicase-catalysed unwinding could be inhibited by the presence of recA protein, we examined its effect on the helicase II reaction in conditions of limiting helicase enzyme. Figure 4a represents the sedimentation of the starting substrate and *b* the results of incubating 2 nmol of substrate DNA (Fig 2a) with 2 μ g SSB protein and 2.4 μ g helicase II for 30 min at 37 °C. The reaction mixture was then sedimented in neutral sucrose. At this concentration of helicase II, 32% of the annealed DNA was separated from the substrate DNA and sedimented more slowly. Addition of 20 μ g recA protein to an identical reaction mixture caused a slight increase in the extent of separation (from 32 to 48%, Fig 4c), indicating that no inhibitory factors were present.

The results shown in Figs 3 and 4 show that recA protein did not act as a helicase. In similar conditions helicases I or II separated the annealed fragment from the single-stranded circle. The addition of recA protein to helicase II did not inhibit the reaction.

Formation of joint molecules by recA protein

The DNA substrate used in these experiments comprised a single-stranded circle with an annealed single-stranded fragment (Fig 2a), and is similar to a gapped duplex. Because recA protein produced joint molecules from intact and gapped duplex molecules^{26,27}, we investigated whether the substrate with a very short duplex region (Fig 2c) also formed joint molecules in the presence of recA protein. Nitrocellulose filters were used in the assay²⁶ because they allow form I DNA to pass but retain both substrate DNA and joint molecules due to their partially single-stranded nature.

To study the formation of joint molecules we incubated 0.2 nmol ³²P-labelled form I Φ X174 DNA and 1.7 nmol sub-

Fig. 3 Neutral sucrose sedimentation profiles showing the separation of a ^{32}P -labelled ΦX174 fragment from ^3H -labelled ΦX174 single-stranded circular DNA by helicase enzymes. The standard reaction mixture was used *a*, without enzyme, *b*, with helicase I, *c*, with helicase I but without SSB protein, *d*, with recA protein, *e*, with recA protein but without SSB protein, *f*, with recA protein and excess homologous ^3H -labelled (+) single-stranded ΦX174 fragments. Sedimentation is to the left. The substrate for the unwinding assay was prepared by digesting ΦX174 form I ^{32}P -labelled DNA with *Hae*III restriction enzyme (Bethesda Research Laboratories) and separating the products on a 5% polyacrylamide slab gel. The 194-base pair fragment was eluted from the gel, concentrated by ethanol precipitation and denatured by heating, followed by rapid cooling. The fragments were annealed with the (+) strands of ΦX174 ^3H -labelled phage DNA. Fragments not bound to the (+) strands were removed by sucrose gradient centrifugation. RecA and SSB proteins were purified as described elsewhere^{27,30}. The standard reaction mixture contained in a total volume of 100 μl , 2 nmol of substrate DNA, 20 mM Tris-HCl, pH 7.5, 25 mM MgCl_2 , 20 mM NaCl, 0.1 mM EDTA, 2 mM dithiothreitol, 2 mM ATP, 1.5 μg bovine serum albumin, 2 μg SSB protein and enzyme to be tested. Incubation was for 30 min at 37°C. The reaction was stopped by the addition of EDTA to 25 mM and SDS to 1% and, after dilution with 0.2 M NaCl to 200 μl , the mixture was sedimented through 5 ml of 5–20% neutral sucrose (10 mM Tris-HCl, pH 7.5, 1 M NaCl, 10 mM EDTA). Sedimentation was carried out in a Beckman SW 50.1 rotor at 45,000 r.p.m. and 20°C for 135 min. Fractions collected from the gradients were counted for radioactivity in Formula 963 scintillation fluid (NEN). $\circ$, ^{32}P , $\times 10^{-2}$; $\bullet$, ^3H , $\times 10^{-3}$.

strate DNA (Fig. 2c) in the presence of 40 μg of recA protein, treated the products with SDS and filtered them through nitrocellulose. The filters retained ~20% of the duplex DNA (Table 1, experiment 1). In control reactions done in the absence of any proteins or with SSB protein alone, a background of 10% of the input duplex DNA was retained. However, in the presence of both 40 μg of recA protein and 2 μg of SSB protein, almost 40% was retained. These results show that recA protein forms joint

molecules from the annealed substrate and form I DNA in conditions in which strand separation was not detected. As in other pairing reactions promoted by recA protein, ATP and Mg^{2+} were required.

The requirement for homology between molecules was also demonstrated with the filter binding assay. Joint molecules were not detected when the annealed substrate DNA and non-homologous ^3H -labelled form I plasmid DNA were incubated with recA and SSB proteins (Table 1, experiment 2). We also investigated whether single-stranded circular ΦX174 DNA, without the annealed fragment, could pair with intact circular duplex DNA (Fig. 2d). Experiments 3 and 4 in Table 1 show that incubation of single-stranded ΦX174 DNA with either ^{32}P -labelled form I ΦX174 or ^3H -labelled form I plasmid DNA (Fig. 2d) in the presence of recA and SSB proteins did not lead to retention of the duplex DNA. This shows that the partially single-stranded and partially duplex character of the substrate is needed for the formation of joint molecules.

What is the nature of the joint between the two molecules? A joint molecule could be formed by the transfer of one end of the annealed fragment to the duplex. The mechanism responsible for such a reaction might sometimes transfer the entire short fragment and so produce a D-loop which would be detected as a joint molecule in the filter binding assay. To investigate whether the observed binding of the form I DNA was due to the transfer of the ^3H -labelled fragment to the ^{32}P -labelled duplex (to form a D-loop), the reaction was stopped at the end of incubation by the addition of 1 mM $\gamma\text{-S-ATP}$ and the form I DNA was cleaved into small fragments with *Hae*III restriction enzyme. After protein removal by treatment with proteinase K and SDS, the products were sedimented through neutral sucrose. The ^3H -labelled fragments sedimented with the single-stranded circular DNA and none (<3%) was detected at the position of the ^{32}P -labelled restriction fragments which sedimented more

Fig. 4 RecA protein does not inhibit helicase II-catalysed strand separation. The strand separation assay was the same as that described in Fig. 3 legend. The standard reaction mixture was used *a*, without enzyme, *b*, with helicase II, *c*, with helicase II and recA protein. $\circ$, ^{32}P , $\times 10^{-2}$; $\bullet$, ^3H , $\times 10^{-3}$.

his experiment indicates that no detectable transfer of the labeled fragments to the form I DNA occurred, and will be described in greater detail elsewhere³⁸

Results indicate that recA and SSB proteins promote the formation of joint molecules between intact duplex DNA and homologous single-stranded molecules that contain a short duplication (Fig 2c). This pairing reaction occurred in conditions similar to those used in the assay for helicase activity

Homologous pairing between gapped and intact duplexes

Because most models for genetic recombination^{1-5,8} assume that the first steps in homologous pairing involve strand unwinding and the formation of a heteroduplex between the unwound strand and the complementary strand of the homologous duplex (Fig 1a), we looked for evidence that recA protein could promote strand separation

Using le-stranded circular DNA with an annealed fragment (Fig 1), we were unable to detect any helicase activity of recA protein with or without the presence of SSB protein (Fig 3). Furthermore, homologous pairing does not seem to require extensive strand separation because treatment of gapped molecules with oralen and light to produce a minimum of 1 cross-link per 50 base pairs did not inhibit the formation of joint molecules. However, we found that recA protein, which is known to promote homologous pairing between gapped circular and form I DNA^{26,27}, was also able to induce homologous pairing between form I DNA and ssDNA carrying an annealed fragment (Fig 2c, Table 1), the yield being increased by SSB protein. Although the fragment was only 392 nucleotides long, it was essential for pairing.

In this reaction, the joint molecules could be formed through the transfer of the end of the fragment to the form I duplex while the other end remained bound to the single-stranded circle, thus linking the molecules as in Fig 1A. However, it is difficult to see why the transfer of a short fragment should stop before completion. It is more likely that the transfer would go to completion and the fragment be completely assimilated into the duplex, but no such transfer was detected. If the reaction was not driven to completion, the intermediate structure would presumably dissociate through branch migration³⁹

Although we did not detect strand transfer from the annealed substrate when form I DNA was added, we have found in other reactions that recA protein promotes a strand exchange reaction if the form I DNA is replaced by blunt-ended duplex fragments

that are homologous to and overlap the ends of the annealed fragment³⁸. This exchange might take place by a reaction similar to that described for the formation of D-loops from single-stranded circular and linear duplex DNA^{38,40}

How are these observations to be reconciled? We suggest that recA protein can process some DNA substrates via D-loop formation involving strand transfer, while it may process others by four-stranded complementary pairing (Fig 1B), perhaps similar to that proposed from studies with DNA models^{41,42}, or by another mechanism involving three-stranded side-by-side pairing. Complementary hydrogen bonding may occur between two duplexes without strand separation and involves a four-stranded helical structure with contacts in the major groove⁴². We attribute the formation of joint molecules between duplex and gapped circles, described here and in recent papers^{26,27}, to these latter mechanisms

How does recA protein promote homologous pairing between two duplex molecules? The only structure known to cause exchanges with a high efficiency in intact cells is a duplex containing a post-replication gap²⁹. Purified recA protein binds cooperatively to single-stranded but not duplex DNA. It also binds to gapped duplex DNA and shows high ATPase activity, almost as great as when bound to ssDNA³⁰. To explain this we suggest that it binds initially at the gap and spreads along the adjacent duplex (Fig 1B, I), forming a bound state which may be transient as ATP is being hydrolysed. Homologous pairing can take place in conditions in which the DNA is loaded with recA protein. The initial nonspecific contact between gapped and intact molecules (Fig 1B, II) presumably leads to a search for homology and the formation of joint molecules with the base sequences aligned (see XYZ in Fig. 1B, III). Once homologous contacts are made, the DNA molecules are held together by hydrogen bonds which seem to be stable, even when deproteinized with SDS and proteinase K but are, however, alkali labile^{26,27}

The joint molecules formed by homologous pairing may then be acted on by the cutting in *trans* enzymes^{43,44}, opening the way for strand exchanges^{38,40} and formation of recombinants. Future work will determine the validity of this proposal for homologous pairing, the details of the structures involved in the joint molecules, and the way in which they are cut and joined to produce recombinants

We thank Drs H. Hoffmann-Berling and M. Abdel-Monem for helicases I and II and Drs C. DasGupta, T. Shibata, R. Cunningham and C. Radding for sending us their manuscript before publication. This work was supported by USPHS NIH grants GM 11014, CA 06519 and AM 09397

Emission in the Lyman bands of H₂ has been detected in an extreme ultraviolet (EUV) spectrum of T Tauri and its adjacent nebula, obtained with the international UV explorer (IUE) satellite. We report here that the emission is in a progression which can be excited through fluorescence with the red wing of the H Ly α line, as found also in the solar atmosphere¹. The observed EUV fluxes, absence of other progressions and the flux in the previously observed² 1-0 S(1) IR line support a model where collisional rather than radiative excitation leads to an excitation temperature of $\geq 2,000$ K.

T Tau is a pre-main-sequence star, with a photospheric absorption spectrum consistent with a spectral type of K0 or K1 according to Kuhl³. It is embedded in nebulosity, from which characteristic low-excitation lines are observed in the visible region of the spectrum⁴. Emission from the $v'' = 1-0$ S(1) line of molecular hydrogen at $2.12 \mu\text{m}$ has also been detected², originating from a region ~ 5 arc s in extent centred on the star. The distance³ to T Tau is ~ 160 pc.

We observed T Tau on 4 November 1980 with the IUE satellite, from the ESA IUE ground station at Villafranca, Madrid. A short wavelength region (1,200–2,000 Å) spectrum was obtained at low spectral resolution ($\Delta\lambda \sim 6$ Å) with an exposure time of 372 min, using the large (21×9.5 arc s) aperture. The spectrum shows emission from both the star and nearby nebulosity which extends to the south. A long wavelength region (2,000–3,200 Å) spectrum was obtained at high spectral resolution ($\Delta\lambda \sim 0.2$ Å) with an exposure time of 176 min, also using the large aperture. Only the stellar emission lines of Mg II (multiplet 1) and Fe II (multiplet 1) are well exposed, many weak emission features are just detectable.

Figure 1 shows tracings through the short-wavelength spectrum of the star and nebulosity. Figure 2 shows the profiles of the stellar Mg II lines. The short wavelength spectra have been extracted from the GPHOT image by procedures discussed elsewhere⁵, and making use of the Rutherford-Appleton Laboratory IBM 360/195 computer. The long-wavelength spectrum is as provided by the IUE VILSPA processing system.

The strongest features in the short-wavelength spectrum may be attributed to transitions in O I, C II, C IV, Si II, Si III and C III

commonly observed in the EUV spectra of late-type stars² of these have been observed previously in a shorter exposure of T Tau⁶, and also in the T Tauri-type stars R U Lupi⁷ and Aur⁸.

In addition to these lines, emission features of lower intensity are observed at the wavelengths listed in Table 1. These are only lines which can be positively detected in the spectrum of the nebulosity. We identify the lines listed in Table 1 as transitions in the Lyman bands of H₂. These particular lines have been observed previously in the EUV spectrum of a sunspot⁹ it would be difficult to make a positive identification of emission without this prior knowledge. The observed wavelengths correspond to those of the strongest H₂ lines seen in solar spectrum, namely the P(5) and R(3) transitions in the $v'' = 1$ to $v' = 3, 6, 7$ and 8 bands. The laboratory wavelengths in Table 1 are taken from ref. 9. The 1-4 and 1-5 bands should be weaker, according to the calculated transition probabilities¹⁰ of the Sun.

Fig. 1 Low resolution spectrum of T Tau in the region 1,200–1,600 Å. In addition to the common species indicated, the P(5) and R(3) lines of H₂ in the $v' = 1$ to $v'' = 3, 6, 7$ and 8 are observed. The upper spectrum originates in the star plus nebula in the line of sight. The lower spectrum originates in the adjacent nebulosity, and is plotted on a scale lower by $0.5 \times 10^{-14} \text{ erg cm}^{-2} \text{ s}^{-1} \text{ Å}^{-1}$.

the lines are due to fluorescent emission from the upper level $v' = 1, J' = 4$, which is excited through the $v'' = 2, J'' = 5$ to $v' = 1, J' = 4$ transition, which lies $\sim 26 \text{ cm}^{-1}$ to the red of the rest wavelength (1,215.67 Å) of the atomic H Ly α line. We propose that the same excitation process is occurring in the region around T Tau. The listed fluxes include the line of sight plus the adjacent nebulosity, the latter contributing about 30% of the total. (It is not possible to distinguish between stellar and nebular emission in the line of sight.)

The presence of this emission in the absence of a strong UV continuum has important implications for the excitation of H₂ molecule in such regions. For the observed fluorescent route to be effective, a substantial population of H₂ must reside in the excited $v'' = 2, J'' = 5$ level. It has been proposed that shock heating in addition to excitation by UV radiation is required to account for the intensities of lines of H₂, both around T Tau^{11,12} and in the Orion nebula^{13–15}. Detection of the S(1) 2.12- μm line alone³ did not allow shock excitation to be distinguished from excitation by a strong EUV continuum^{16–18}. The new EUV observations favour a collisional excitation model, probably associated with shock heating. The likely relevance of H Ly α

Table 1 Lines of H₂ observed in T Tau

λ (Å)	Flux at Earth ($\text{erg cm}^{-2} \text{ s}^{-1}$)	v'	v''	Proposed identification	λ lab ⁹ (Å)
1,258	$\approx 4.2 \times 10^{-14}$	1	3	R(3)	1,257.80
1,272	8.6×10^{-14}			P(5)	1,271.93
1,431	1.0×10^{-13}	1	6	R(3)	1,431.01
1,446	1.4×10^{-13}			P(5)	1,446.13
1,490	1.8×10^{-13}	1	7	R(3)	1,489.57

1,562	1.7×10^{-13}			P(5) + C I	1,562.41

fluorescence in regions where excited H_2 exists has already been pointed out^{19,20}.

The $H\text{ Ly}\alpha$ emission visible in the IUE spectrum is due mainly to geocoronal emission, and high resolution spectra will be required to investigate the stellar component. However, the $Mg\text{ II}$ lines shown in Fig. 2 give some idea of the shape of the line profile. These lines show strong emission, with the centre of this emission shifted by 50 km s^{-1} to the red of the strong interstellar absorption feature which in this direction, should itself be redshifted by $\sim 10\text{--}20\text{ km s}^{-1}$. As the star has a radial velocity²¹ of only 22 km s^{-1} , and the width of the $Mg\text{ II}$ emission at the star will be at least the value of 120 km s^{-1} observed at the Earth, it can be argued that substantial flux should exist in the red wing of the $H\text{ Ly}\alpha$ line, in particular at $1,216.05\text{ \AA}$, the wavelength at which fluorescent excitation takes place. An estimate of the $H\text{ Ly}\alpha$ flux in the relevant wavelength range can be made by scaling from the $Mg\text{ II}$ flux, which is typically a factor of ~ 4.5 larger than $H\text{ Ly}\alpha$ in a variety of late-type stars²⁵. This gives a flux of $\sim 10^6\text{ erg cm}^{-2}\text{ s}^{-1}$ in the equivalent part of the $H\text{ Ly}\alpha$ line.

Provided all transitions from $v'=1, J'=4$ are optically thin, the measured flux in the $P(5)$ line at $1,505\text{ \AA}$ can be used in conjunction with the expression for the emissivity given by Jordan *et al.*¹⁹ to give

$$\int N(2, 5) I_\nu dV \sim 3.0 \times 10^{33} \quad (1)$$

where $N(2, 5)$ is the population density (cm^{-3}) in the level from which excitation takes place, I_ν is the intensity of the $H\text{ Ly}\alpha$ radiation field ($\text{erg cm}^{-2}\text{ s}^{-1}\text{ Hz}^{-1}$) at the nebula. Allowing for a geometric dilution factor in a medium optically thin to $H\text{ Ly}\alpha$, I_ν can be related to I_ν^* , the intensity at the star. Then

$$I_\nu \sim 1.0 \times 10^{17}/R^2 \quad (2)$$

where R (cm) is the distance at which absorption by H_2 takes place.

The observed relative intensities of the transitions to $v''=3$ and 6 or 7 suggest that the lines to $v''=3$ are marginally optically thick. However, even if the transitions to $v'' \leq 3$ are optically thick, a probability of escape argument for lines from a common upper level shows that the enhancement of the optically thin transitions is only a factor of 1.7. In view of the larger uncertainties this correction has not been applied.

The IR observations show that the H_2 emission originates from a region around the star of $\sim 5\text{ arc s}$ ($1.2 \times 10^{16}\text{ cm}$) in total extent. The spatial distribution in the optical region and in our EUV spectrum is asymmetric and less than 10 arc s in extent. We adopt an emitting volume $F4\pi R^2 dl$, where F is some fraction of the spherical shell of radius R . The column density in the 2, 5 level is then

$$\int N(2, 5) dl \sim \frac{1}{F} 2.4 \times 10^{15} \text{ cm}^{-2} \quad (3)$$

Similarly the observed flux in the $S(1)$ transition and transition probability²² can be used to give

$$R^2 \int N(1, 3) dl \sim \frac{1}{F} 2.2 \times 10^{47} \quad (4)$$

Equations (3) and (4) then give $N(2, 5)/N(1, 3)$ as a function of R , assuming that the emitting volumes are the same. The value

Fig. 2 High resolution spectrum of the $Mg\text{ II}$ resonance lines in T Tau. The arrows mark the rest wavelength at the star. Narrow interstellar lines appear in broad asymmetric stellar lines.

of the excitation temperature, T_{exc} , required to give this population ratio may then be found.

Table 2 gives values of R , the radius of the shell, for temperatures between 1,000 and 3,000 K. These are somewhat smaller than the value of $6 \times 10^{15}\text{ cm}$ found from the IR observations. A larger flux in the stellar $H\text{ Ly}\alpha$ emission would result in a larger value of R . Even allowing for an order of magnitude underestimation of I_ν^* would lead to $T_{\text{exc}} \geq 1,500\text{ K}$.

A further estimate of T_{exc} can be made by using the observed upper limit to the flux at $1,365.7\text{ \AA}$, where the strongest member of the $P(1)$ progression, which can be excited by $H\text{ Ly}\beta$, should occur²³. The ratio of the flux at $1,365.7\text{ \AA}$ to that in the $1,505\text{ \AA}$ line gives

$$N(2, 5)/N(0, 1) \geq 2 \times I(\text{Ly}\beta)/I(\text{Ly}\alpha).$$

Using $I(\text{Ly}\beta)/I(\text{Ly}\alpha) \sim 10^{-2}$, as in the Sun, results in $T_{\text{exc}} \geq 2,700\text{ K}$.

The mass column density (from equation (3) with $F \leq 1$), emitting mass and lower limits to $N(H_2)$ for a filled shell, are also given in Table 2. These mass column densities are consistent with lines to $v'' \leq 3$ being optically thick. Solutions with $T_{\text{exc}} \leq 1,000\text{ K}$ are excluded by the upper limit imposed by known⁴ visual extinction to the star and nebula.

Finally we may compare the results of Beckwith *et al.*² who adopted Kwan's model¹⁵ for excitation by a low velocity shock and subsequent emission through the $1\text{--}0\text{ S}(1)$ line. With $v_{\text{shock}} \sim 15\text{ km s}^{-1}$ they find $N(H_2) \sim 2 \times 10^4\text{ cm}^{-3}$. Adopting recent calculations of dissociation speeds²⁴, the upper limits to the shock velocity can be found as a function of $N(H_2)$ and are given in Table 2. In the absence of a strong EUV continuum it would be difficult to destroy the H_2 once formed.

We conclude that the EUV observations are consistent with a model where H_2 is at an excitation temperature of $\geq 2,000\text{ K}$, and that the basic excitation mechanism is collisional rather than radiative.

Table 2 Parameters of the emitting region as a function of T_{exc}

T_{exc} (K)	R (10^{15} cm)	$\int N(H_2) dl$ (cm^{-2})	$N(H_2)$ (cm^{-3})	$\mathcal{M}$ ($M_\odot$)	v_{shock} (km s^{-1})
1,000	0.38	$\geq 2.0 \times 10^{21}$	$\geq 5.3 \times 10^6$	5.6×10^{-6}	<21
1,500	0.91	$\geq 5.7 \times 10^{19}$	$\geq 6.3 \times 10^4$	9.9×10^{-7}	<22
2,000	2.10	$\geq 4.9 \times 10^{18}$	$\geq 2.3 \times 10^3$	4.4×10^{-7}	<32
3,000	3.60	$\geq 7.9 \times 10^{17}$	$\geq 2.2 \times 10^2$	2.0×10^{-7}	<51

A water vapour maser in the Large Magellanic Cloud

E. Scalise Jr

CRAAM/INPE: Instituto de Pesquisas Espaciais, Conselho Nacional de Desenvolvimento, Científico e Tecnológico-CNPq, CP 515, 12200-São José dos Campos, SP, Brasil

M. A. Braz

CNPq-Observatório Nacional, Rua Pará, 277, 01243-São Paulo, SP, Brasil

Surveys of the Large Magellanic Cloud (LMC), the closest satellite galaxy to our Solar System, for water vapour sources of measurable intensity have so far yielded negative results. These searches, by Johnston *et al.*¹ and Kaufmann *et al.*², with detection limits of about 150 and 20 Jy (1 Jy = 10^{-26} W m⁻² Hz⁻¹), respectively, suggest that any water vapour masers that exist in the LMC are much weaker than the sources recognized in our own Galaxy and in several more distant galaxies^{3–5}. We now report the results of a survey using the 45-ft Itapetinga radio telescope which shows the presence of a water vapour maser in the N159 region of the LMC.

The survey was carried out in 1979–80. Upper detection limits of about 1.2 Jy were attained with the use of long integration times and a maser amplifier front-end, the total system temperature ranging from 250 to 400 K. Spectral information was provided by a 47-channel spectrometer, 100-kHz bandwidth filter bank, giving a velocity resolution of 1.35 km s⁻¹. Two vertically polarized feed horns were used in beam-switching the on-off observing mode. Each independent observation was taken with 30 min integration. We selected observations made in good weather conditions and our data were corrected for atmospheric attenuation effects by assuming an average atmospheric optical depth of 0.2. The data were also corrected for random attenuation and elevation gain dependence.

We concentrated our search for the $J = 6_{16} - 5_{23}$ transition of the water maser line ($\nu = 22235.08$ MHz) in two of the strongest H(II) regions in the LMC⁶—N157 (ref. 7, 30 Doradus) and N159—and in two dark nebulae⁸—Hodge 47 and Hodge 52. Huggins *et al.*⁹ studied these four regions in their carbon monoxide survey.

Water vapour emission was detected in only one of these four positions, N159, and its spectrum is shown in Fig. 1. It presents two components, one 8 km s⁻¹ wide with a narrow feature of 7.2 Jy at 233.6 km s⁻¹, and the other with a feature of 3.2 Jy at 213.9 km s⁻¹.

It is interesting that the water maser we discovered in N159 coincides with the lowest colour temperature far-IR source detected by Werner *et al.*¹⁰ in the LMC—30 Doradus—which is also the strongest source. A large CO cloud, 24 pc in diameter, was found in this direction⁹. Other molecules such as H₂CO (ref. 11), OH (ref. 12) and CO (ref. 9), have been discovered at this position in the LMC, with velocities almost coincidental with the H₂O velocity.

Regarding the intensity of this maser, it would be a strong source of 8×10^4 Jy if placed at the distance of the Orion Nebula, but when compared with the W49 masers, it is much weaker in terms of total luminosity¹³.

A negative result was obtained for the 30 Doradus nebula, probably due to the fact that its core contains a large number of young OB stars¹⁴ responsible for the ionization of the molecules.

Fig. 1 Water vapour spectrum of N159 (RA 05 h 40 min 24 s DEC. $-69^{\circ}46'0.1950.0$). The main feature appears at 233.6 km s⁻¹ with respect to the Local Standard of Rest.

Hence, one should search for water farther away from its nucleus. Hodge 47 and 52 also showed no line emission.

Our search for water masers in the direction of the Large and the Small Clouds will continue, and we hope that the results improve our knowledge not only of masers but also of our closest irregular Magellanic-type galaxies.

This research resulted from a Brazil-US bilateral scientific agreement through the national agencies CNPq and NSF, respectively. The maser receiver was developed at Haystack Observatory under the direction of Dr S. H. Zisk. Partial support was received from Brazilian science agencies FINEP and FAPESP.

Discrete chorus emissions observed at a low latitude ground station

Birbal Singh, Ram Prakash & Hari Singh

Department of Physics, RBS College, Bichpuri,
AGRA-283 105, India

Discrete chorus emissions observed for the first time at the low latitude ground station Bichpuri, Agra (geomagnetic lat. $17^{\circ}12' \text{ N}$, $L \sim 1.1$) are reported here. The emissions are of the riser type and occurred in the narrow frequency range 1.7–3 kHz. We show that these emissions are generated in the equatorial plane near $L = 1.2$ as a result of cyclotron resonance between whistler mode waves and the inner radiation belt relativistic electrons of energy 3–5 MeV, and propagated to the low latitude ground station under the influence of the horizontal density gradients of the equatorial anomaly.

Using conventional equipment consisting of an antenna, transistorized pre and main amplifiers and a magnetic tape recorder, we started routine observations of whistlers at a low latitude ground station of Bichpuri between January 1979 and July 1979. Bichpuri is in a noise-free rural area $\sim 11 \text{ km}$ west of Agra. The observations were made at night (18.00–06.00 h LT) during the first 10 min of every hour, but, the duration of the recording was increased whenever the whistler activity was found to be high. On 12 January 1979, which was a magnetically quiet day ($K_{p\text{max}} = 3$), we observed nine discrete rising emissions between 19.25 and 20.40 h LT. Some of these emissions, shown in Fig. 1, occurred in a narrow frequency range between 1.7 and 3 kHz with the rate of change of frequency with time (df/dt) between 2 and 3 kHz s^{-1} . The 10 ms structure in the spectra of these emissions is due to the instrument. Such structures (time interval $\sim 1.5 \text{ s}$) have also been observed in high latitude periodic emissions reported by Helliwell¹ (Fig. 7.21). Figure 1a, where two rising emissions are shown, consisted of four emissions; the other two occurred somewhat later. However, all four emissions are shown on a different frequency–time record in Fig. 2. An interesting feature of these emissions is that the time interval between the consecutive emissions is approximately in a geometrical progression. Further, the frequency ranges of first

and third emissions are slightly different from those of the other two emissions.

Hitherto, discrete chorus emissions have been observed only at middle and high latitude ground stations. The lowest latitude ground station where such emissions were received is Chilbolton², Hampshire, UK (geomagnetic lat. 49.8° N , $L = 2.4$). The emissions observed by us could not have been caused by a fault in the equipment because several whistlers, with dispersions in the range $19\text{--}35 \text{ s}^{1/2}$ were also observed by the same equipment. As these riser emissions differ markedly in frequency and df/dt from those of the riser whistlers observed earlier at the low latitude ground station of Gulmarg³ (geomagnetic lat. $24^{\circ}10' \text{ N}$), the possibility that these emissions are also riser whistlers is ruled out. Further, the possibility that these emissions are high latitude discrete chorus emissions which have propagated to our low latitude ground station in the Earth-ionosphere wave-guide mode of propagation³ is also ruled out because there is a strong absorption band in the frequency range 2–5 kHz. The possibility that these emissions are generated at high L -values in the vicinity of the plasmapause and propagated to our ground station after successive magnetospheric reflections in a manner similar to those of the ELF hiss observed by satellites in the inner zone^{4,5} does not seem to be tenable. This is because, at the frequency of these emissions, the attenuation losses during various magnetospheric reflections would be high and the waves could not be detected on the ground. Although the exact losses have not been calculated, a rough estimate can be made from the work of Kimura⁶. He has shown from ray tracing computations in a model ionosphere that the amount of attenuation suffered by the waves of frequency 1 kHz from 300 km at 30° N reaching $L = 3$ after 12 successive reflections is $\sim 6 \text{ dB}$. If we include $\sim 4 \text{ dB}$ of losses suffered in the lower region of the ionosphere, then the total loss will be $\sim 10 \text{ dB}$. To reach the plasmapause near $L = 4$, the waves have to undergo some more reflections and consequently suffer more attenuation than 10 dB. As the attenuation increases with frequency, the waves of the chorus emissions generated near the plasmapause would suffer much higher attenuation than 10 dB and may not be observed on the ground. Further, at the base of the F-region ionosphere, the wave normal angles of these waves are such that the downward waves are unlikely to penetrate the lower ionosphere and reach the ground.

Fig. 1 Discrete chorus emissions observed at the low latitude ground station of Bichpuri. a, 19.27 IST; b, 19.54 IST; c, 19.48 IST; d, 19.53 IST.

Fig. 2 Risers with time interval increasing in geometrical progression.

Thus we believe that these emissions are generated in the equatorial plane in the inner zone radiation belt ($L \sim 1.2$). Cyclotron resonance between whistler mode waves and the inner zone radiation belt electrons seems to be the possible generation mechanism for two reasons: (1) this mechanism has been found to account for the frequency-time spectra of middle and high latitude discrete chorus emissions adequately²; and (2) it also occurs in the inner radiation belt⁷. Below $L = 1.2$ electron losses are dominated by atmospheric scattering^{7,8} resulting in the small life time and density of the energetic electrons and hence the emissions observed by us cannot be generated at the top of the field line corresponding to Bichpuri. These emissions cannot be generated at L -values > 1.2 for the reasons to be stated later. To test the cyclotron resonance as the possible generation mechanism for these emissions, we calculated the resonant energy of the involved electrons and growth rates at $L = 1.2$ in the equatorial plane. The resonant energies for various frequencies of the emissions were calculated from the expression⁵.

$$E_{11} = (\gamma_r - 1)m_0c^2 \quad (1)$$

in which m_0 is the rest mass of electron, c , the velocity of light in vacuum and γ_r , the relativistic factor to be obtained from the relation⁵

$$\gamma_r - 1 \equiv \left(\frac{\tilde{\Omega}}{\omega_p}\right)^2 \left(\frac{\tilde{\Omega}}{\omega}\right) \left(1 + \frac{\Omega^+}{\omega}\right) \quad (2)$$

where $\tilde{\Omega}$ is the electron gyrofrequency, Ω^+ , the proton gyrofrequency, ω_p , the plasma frequency and ω , the wave frequency. The plasma frequency ω_p was calculated from the ionospheric model of Singh⁹ which yielded an electron density of 8.13×10^3 electrons cm^{-3} at $L = 1.2$. The calculated resonant energies, of the order of 3–5 MeV, are shown in Fig. 3a. For calculating the growth rate we followed expression (2.20) of Kennel and Pet-

schek¹⁰, which, for the case $\omega \ll \tilde{\Omega}$, reduces to

$$\gamma = \pi \tilde{\Omega} \eta A \quad (3)$$

where η is the ratio of the density of energetic electrons to that of thermal electrons and A , the pitch angle anisotropy. To obtain the density of energetic electrons at $L = 1.2$ we considered observed intensity versus L -value curves (energy > 1 MeV) given by Katz¹¹ for the inner zone radiation belt. The curve indicated a flux of 3×10^6 electrons $\text{cm}^{-2} \text{sr}^{-1} \text{s}^{-1}$ at $L = 1.2$ which yielded a density of 3–5 MeV electrons $\sim 1.26 \times 10^{-3}$ electrons cm^{-3} . A was calculated from the relation¹⁰ $A = \frac{1}{2} / \log_e(\frac{A_0}{\alpha_0})$ (α_0 being the equatorial loss cone angle, mirror height = 100 km) and found to be 2.08 which is approximately the same as calculated by Ashour-Abdalla¹² at $L = 1.2$ ($P = 250$). If we assume a pitch angle distribution of the form $\sin^m \phi$ ($m = 4$, and ϕ is the pitch angle) and compare the calculated pitch angle versus intensity curve with that of Katz¹¹, the two distributions are found to be nearly the same. Thus the value of the anisotropy $A = 2.08$ at $L = 1.2$ is justified. By substituting the values of $\tilde{\Omega}$, η and A in equation (3), the growth rates for various frequencies of the emissions were calculated and found to be $\sim 3 \text{ rad s}^{-1}$. This result indicates significant wave amplification.

Now we consider how the chorus emissions were propagated to our low latitude ground station. Suitable ducts do not exist in the low latitude ionosphere and non-ducted waves are not observed on the ground. However, Bullough *et al.*¹³ have reported the observation of VLF and ELF emissions in the Ariel 3/4 satellites inside the equatorial anomaly region. The equatorial anomaly is a well-established afternoon-evening phenomenon. Thus it is possible that the low latitude chorus emissions were propagated to our ground station under the influence of the diminishing phase of the equatorial anomaly. To verify this we calculated ray paths for the frequencies of the chorus emissions from $L = 1.2$ to the base of the F-region ionosphere (120 km) in an ionospheric model representing the diminishing phase of the equatorial anomaly. The diminishing phase of the anomaly was assumed to have a constant electron density distribution within $\pm 5^\circ$ of the equator instead of a trough at the equator. This distribution was obtained from the model $N = N_{eo} \exp \alpha (\sin \theta - \beta)$ of Singh⁹ where the value of α was taken to be 11 for the negative horizontal density gradient between 22° and 5° and zero for no ionization variation between 5° and the equator. The ray paths computed for the frequencies of the observed chorus with the initial wave normals along the geomagnetic field line at the equator ($\Delta_0 = -90^\circ$) arrived within 18.5° and 19° latitudes at 120 km, with the final wave normals almost vertically downward ($\Delta_f \approx 178^\circ$) indicating that the corresponding waves would penetrate the lower ionosphere and be observed on the ground. One of the ray paths for the frequency of 3 kHz is shown in Fig. 3b. The ray paths computed from higher L -values of 1.24 and 1.47 arrived at 24° and 45° latitudes respectively with the wave normals not vertically downward. Such waves would not be observed on the ground. Thus the observed chorus emissions were generated at $L = 1.2$ and

Fig. 3 a, The computed resonant energies at $L = 1.2$. b, Ray path for the frequency of 3 kHz. Δ_0 and Δ_f are the initial and final wave normal angles (angles between the wave normal and the vertical, measured from the vertical, positive in a clockwise direction).

propagated to the ground station under the influence of the favourable density gradients of the equatorial anomaly. The growth of these emissions at 1.7 kHz is due to the resonance between the energetic electrons and whistler mode waves of frequency lower than 1.7 kHz and termination of emissions at ~3 kHz is due to the absorption by the thermal background plasma in the interaction region¹⁴. The detailed mechanism in which the four emissions of Fig. 2 were generated with two of them having different upper and lower cutoff frequencies is under investigation and the result will be published elsewhere.

The occurrence of natural whistlers and emissions is a rare phenomenon at our ground station. During the 7 months of observation, we recorded whistlers on four occasions and emissions on one occasion only. The rare occurrence is believed to be due to non-availability of suitable ducts in the low latitude ionosphere. The emissions observed on 12 January 1979 between 19.25 and 20.40 h LT are due to fortuitous presence of favourable density gradients of the equatorial anomaly in the low latitude ionosphere. These emissions, although received only once at our ground station, indicate their origin in cyclotron resonance at low L -values in the ionosphere. Unfortunately, satellite data on inner zone electrons corresponding to the period during which the emissions were observed are not available to confirm the result. However, more data on these emissions and simultaneous satellite data on energetic electrons would be useful for studying the pitch angle scattering and precipitation of energetic particles as a result of cyclotron resonance at low L -shells. We have therefore continued the observations of these emissions in our ground station.

We thank Dr D. L. Carpenter for valuable suggestions and Dr S. S. Agrawal for help with the sonagraph.

High propagation rates of explosions in large volumes of gaseous mixtures

S. R. Moore & F. J. Weinberg

Department of Chemical Engineering and Chemical Technology, Imperial College, Prince Consort Road, London SW7 2BY, UK

To account for the level of damage observed following unconfined vapour cloud explosions of the kind that occurred at Flixborough in 1974, flame speeds of the order 10^2 m s^{-1} have had to be postulated^{1,2}. Detonations (in which reaction is initiated by adiabatic compression in a shock wave) are not thought to be involved, whilst deflagrations (in which molecular and turbulent transport processes from the flame bring the reactants to a state of rapid reaction) do not seem capable of producing sufficiently high velocities. We suggest here that radiation from a large enough body of burnt products could be sufficient to produce multi-point initiation ahead of the flame by igniting particles, especially those consisting of loose aggregates of fine fibres. Although we thought initially that the hazard would chiefly be due to particles of flammable materials, such as cotton waste and other 'fluffy' aggregates of cellulosic substances, we show below that non-flammable materials are also hazardous.

Fig. 1 Minimum ignition times for propane-air (~3.8% propane) ignition by Kaowool (O) and cotton wool particles (□).

Whilst the emissivities of combustion products are very small at optical path lengths encountered in normal practice, they become appreciable for the very large clouds of burnt and burning gases characteristic of vapour cloud explosions. The black-body radiation corresponding to stoichiometric flame temperatures is of the order of 1 MW m^{-2} . In view of the difficulties of arranging and monitoring large scale explosions of premixed reactants, existing measurements have generally been confined to large experimental fires³⁻⁵, usually burning pools of liquid fuels (see, however, ref. 5). These are diffusion flames in which burning does not occur uniformly throughout the gas but is confined to a relatively thin peripheral layer. Radiation fluxes measured near such flames are of the order of $100\text{--}200 \text{ kW m}^{-2}$.

It is easy to show that quite sporadic ignitions ahead of the main front would yield a sufficiently enhanced flame speed. Defining flame speed in terms of the rate of consumption of a given volume of reactants—which also defines the increased rate of generating volume of hot products—multiple ignitions increase total flame area and decrease the distance each flame front has to cover to complete burn-out. From simple geometrical considerations the 'magnification' of the apparent flame speed resulting from multiple ignitions, separated by distance x across a cloud of linear dimension X , is approximately $2X/x$ times the normal propagation rate, and this does not take into account additional effects of turbulence. Note that the present hypothesis is not intended to supersede other possible mechanisms which have been postulated. We wish rather to draw attention to a very significant additional effect which must be taken into account if it occurs at all.

A few order-of-magnitude calculations were carried out on the likely rates of temperature rise of particles subjected to such radiation, to check whether the concept was reasonable. Using a mass/irradiated area ratio of 0.02 kg m^{-2} and a specific heat capacity of $1.7 \text{ kJ kg}^{-1} \text{ K}^{-1}$ (typical for cellulosic materials) rates of temperature rise of the order $10^4\text{--}10^5 \text{ K s}^{-1}$ are obtained. Typical auto-ignition temperatures would, therefore, be expected to be reached in $10^{-2}\text{--}10^{-1} \text{ s}$. Moreover, there are likely to be cooperative effects between flammable mixture and heated particle as regards the ignition criterion: the ignition temperature or ignition energy may be considerably lower for a combustible particle in a flammable mixture than that for either a combustible particle in air or for an inert particle in a combustible mixture. It therefore seems reasonable that the available radiation flux could raise the temperature of a particle, irrespective of its size (that is, over dimensions larger than the quenching distance) to a reasonable ignition temperature in the time during which a sufficient radiation source persists.

The short duration of the ignition time lag means that it is the growth of the initial radiation source to a size giving sufficient emissivity that is likely to take the longest time. Thereafter ignition of all the centres irradiated at the same flux may be virtually simultaneous, irrespective of the time lag affecting each

Fig. 2 Effect of gas mixture composition on minimum ignition times (flux = 350 kW m^{-2}) of Kaowool (○) and cotton wool particles (□).

of them. Due to the attenuation of radiation with distance, such initiation will, however, occur progressively ahead of the advancing flame front. The over pressures generated will depend on this rate of progression but the contribution of radiation ignition will not fall to zero until the propagation rate is so fast that the ignition lag, integrated over the range of radiation fluxes ahead of the front, remains incomplete by the time the front reaches the particle.

To study the concept, various particles were irradiated in a flammable atmosphere by a small continuous-wave CO_2 laser constructed in these laboratories with a nominal power of 20 W. The distribution of radiation flux across the beam was determined calorimetrically and peaked at 400 kW m^{-2} . The irradiated particles were suspended on quartz fibres above a burner mouth discharging pre-mixed propane-air in various proportions, metered by rotameters. The time to ignition was measured as a function of radiation flux and mixture strength for each type of particle. The onset of ignition was monitored by means of an ionization probe connected to an oscilloscope. Synchronization of particle irradiation with the start of the time measurement was achieved by placing a steel shutter in the laser beam and connecting this to the trigger input of the oscilloscope. Some results are shown in Figs 1 and 2.

As might be expected the dependence of the results on the form of aggregate of the particles is more complex than simple theory suggests. For compact aggregates such as small pieces of paper, charring occurs without producing ignition in our experimental conditions. However, loose aggregates of fine fibres, such as cotton wool, will ignite in a small fraction of a second at a radiation flux $< 10\%$ of that corresponding to the black-body radiation at stoichiometric flame temperatures (see Fig. 1) and well within the range of values measured near large fires. Note that non-flammable materials in this form of aggregate, such as the refractory 'Kaowool' produce ignition at least as readily (in fact in less time—see Fig. 2).

Presumably the effectiveness of such particles in producing ignition is due to their low heat capacity for a given volume and area irradiated. The mechanism is now being studied in greater detail. In this context, note that the fibre diameters of Kaowool and cotton wool are $5 \mu\text{m}$ and $20 \mu\text{m}$ respectively. It also seems that the evolution of blanketing vapour from the fibres must be considered in parallel with the rise of temperature in time. Thus it seems likely that the rich limit of ignitable compositions of the mixture is extended to the flammability limit in the case of Kaowool (see Fig. 2) because, unlike cotton wool, it does not evolve any flammable vapour.

The conclusion that materials in this form of aggregate are readily ignited by levels of radiation flux corresponding to those measured in large experimental fires, seems to us of far-reaching importance. Note that the kind of aggregate most conducive to ignition by radiation is also the most likely to be raised by a blast

wave or convection current, due to its low free-fall velocity. If the hypothesis is correct, it suggests that the practical hazard may be alleviated, for example by spraying and thus retaining dangerous dusts on wetted surfaces.

We thank Professor H. Gg. Wagner for introducing F.J.W. to this problem and for many helpful discussions, and Dr R. W. Dibble for building the CO_2 laser.

Decomposing the IR absorption spectra of diamonds

Gordon Davies

Wheatstone Physics Laboratory, King's College, Strand, London WC2R 2LS, UK

Nitrogen is the most important impurity found in natural diamonds, affecting properties as diverse as colour¹ and thermal conductivity². Consequently it is important to distinguish between the different molecular forms adopted by the nitrogen. Improved data for obtaining the relative concentrations of two of the most common molecular forms are now presented. These data are then applied to a set of diamonds taken from one source and it is confirmed that the relative concentrations of the different forms of the nitrogen are intimately related to each other.

Most natural diamonds (perhaps 98%)³ contain their nitrogen predominantly in the A molecular form, believed to be a pair of nearest neighbour substitutional atoms⁴, as well as in other aggregated forms. These other forms are the N_3 and N_9 centres which may be identified by UV spectroscopy¹, the B aggregates and the platelets. The platelets produce⁵ a clearly resolved absorption peak at $1,370 \text{ cm}^{-1}$ ($7.3 \mu\text{m}$) as shown in Fig. 1. However, the A and B aggregates give overlapping absorption (Fig. 1). In the spectral region of Fig. 1, pure diamonds are essentially transparent.

To separate the A and B spectra we can take the ratio $m = \mu(7.8)/\mu(8.5)$ of the absorption coefficients measured at $7.8 \mu\text{m}$ ($1,280 \text{ cm}^{-1}$) and at the peak absorption near $8.5 \mu\text{m}$ (near $1,175 \text{ cm}^{-1}$). From m we can obtain the ratio $r = \mu_{7.8}^A/\mu_{7.8}^B$ of the absorption produced separately by the A and B aggregates at $7.8 \mu\text{m}$. Although existing data⁶ relating m and r have been used⁷⁻⁹ these were based on a very few largely unsuitable diamonds and are slightly incorrect when r is large. For the present study diamonds were selected for good homogeneity, with large faces (about $3 \times 5 \text{ mm}^2$) and with optimum absorption strengths (giving minimum transmissions of about 40% of the incident light). It is now found that

$$r = (2.72m - 1)/(1 - 0.41m) \quad \text{when } m < 1.5$$

and

$$r = (1.88m - 1)/(1 - 0.5m) \quad \text{when } m > 1.5$$

(It is preferable to use two expressions, depending on the value of m , as the wavelength of the peak absorption near $8.5 \mu\text{m}$ varies with the A to B admixture, as is obvious from Fig. 1.) Hence

$$\mu_{7.8}^A = \mu(7.8)r/(1+r); \quad \mu_{7.8}^B = \mu(7.8)/(1+r) \quad (1)$$

where $\mu(7.8)$ is the total absorption measured at $7.8 \mu\text{m}$. An alternative way to obtain r (for example in strongly absorbing diamonds) is to use the absorption ratio m' measured at $9.9 \mu\text{m}$

(1,015 cm⁻¹) and 9.1 μm (1,100 cm⁻¹), $m' = \mu(9.9)/\mu(9.1)$, giving

$$r = (0.795 - 1.164m') / (0.124m' - 0.0333)$$

and

$$\begin{aligned}\mu_{7.8}^A &= \mu(9.1)r / (0.125r + 1.164); \\ \mu_{7.8}^B &= \mu(9.1) / (0.125r + 1.164)\end{aligned}\quad (2)$$

Equations (1) and (2) are believed to give $\mu_{7.8}^A$ and $\mu_{7.8}^B$ correct to $\pm 5\%$ of the total absorption at 7.8 μm.

As an application of these results we consider the relationship obtained by Brozel *et al.*⁷ on the platelet A and B absorption in different diamonds. They worked with specimens taken from arbitrary sources. As the distribution is determined thermodynamically¹⁰ we may obtain cleaner statistics by using specimens from one growth environment. Forty-seven diamonds from an eclogitic environment¹¹ in the Premier Mine (South Africa) gave the relationship shown by the dots in Fig. 2 for the variation of platelet absorption at 7.3 μm divided by $\mu(7.8)$ with the fraction of $\mu(7.8)$ produced by the A aggregates. (All these quantities are measurable directly from the IR spectra.)

For $\mu_{7.8}^A/\mu(7.8) > 0.5$ the data lie on a remarkably uniform trend with three times less scatter than reported by Brozel *et al.*⁷. However, for smaller values of this ratio the data deviate from Brozel's curve⁷ (shown by the line in Fig. 2 after transforming to the axes used here and adjusting the ordinate to allow for the arbitrary scale used in ref. 7). Supplementing the Premier

Fig. 1 IR absorption spectra of diamonds containing predominantly A and B aggregates.

Fig. 2 The variation of (platelet peak absorption divided by total 7.8 μm absorption) with the ratio r of the absorption at 7.8 μm produced separately by the A and B aggregates. Diamond A has a total 7.8 μm absorption of $\mu(7.8) = 0.5 \text{ cm}^{-1}$, far lower than that of most of the other specimens, which had $5 \leq \mu(7.8) \leq 50 \text{ cm}^{-1}$. ●, Diamonds from the Premier Mine; ×, random species. The line is taken from ref. 7 after transformation and scaling.

diamonds with random specimens produces a scatter and not the unambiguous approach to the origin given by Brozel *et al.*⁷.

The significance of these results is not limited solely to the somewhat esoteric relationships plotted in Fig. 2. It has been shown¹²⁻¹⁴ that single substitutional nitrogen atoms are able to migrate through the diamond lattice at temperatures around 1,800 K, apparently by a vacancy-enhanced diffusion process¹⁴. The immediate end product of the migration is self-trapping to form the A aggregate of nitrogen. Likewise the A aggregates may be broken into single atoms by heat treatment (for example, at 2,250 K)⁷. The equilibrium established by the nitrogen between the single and the paired form depends on the temperatures experienced by the diamonds¹⁰. The other aggregated forms of nitrogen mentioned above also take part in the equilibration process^{9,10}. Viewed in this context, the relationships shown in Fig. 2 suggest that, in principle, the relative concentrations of nitrogen in a given diamond can be used to estimate the temperatures experienced by that diamond since its formation; the conditions prevailing at its formation can be determined from the nature of the inclusions trapped within it at the time of growth¹¹. As well as being of interest to the geologist, this approach is important to the gem industry because the restructuring of the nitrogen impurity by heat treatment can improve the colour of a diamond¹⁷.

I thank J. W. Harris for the Premier Mine diamonds, Z. E. Ciechanowska for running preliminary spectra and A. T. Collins for experimental advice.

Quantitative retention of magmatic argon in a glassy basalt

David E. Fisher

University of Miami, Rosenstiel School of Marine and Atmospheric Science, 4600 Rickenbacker Causeway, Miami, Florida 33149, USA

Basalts erupted in deep waters commonly chill sufficiently rapidly to form a glass outer skin. Due to the rapid chilling and the high hydrostatic pressures, magma-ambient gases and in particular the rare gases may be trapped within this glass¹⁻³. Several theoretical investigations have examined the relationship of the trapped $^{40}\text{Ar}/^{36}\text{Ar}$ ratio to the history of terrestrial degassing and formation of the atmosphere⁴⁻¹¹. These measurements have not yet, however, answered the fundamental questions of whether the mantle $^{40}\text{Ar}/^{36}\text{Ar}$ ratio varies significantly either vertically within the Earth and/or from one geographic locality to another, or even whether a quantitative estimate of the magmatic concentration and isotopic ratio at any given location is in fact obtainable. This report deals with the last of these questions. Our data indicate that the answer is in the affirmative.

In any sample, the Ar actually measured will consist of unknown proportions of a trapped magmatic and a contaminating atmospheric component, and it is possible that the trapped magmatic component may not be quantitatively retained in the

Table 1 Ar data measured in seamount P-50 (5°59'S, 98°09'W)

Sample no.	Description	^{36}Ar ($10^{-10} \text{ cm}^3 \text{ g}^{-1}$)	$^{40}\text{Ar}/^{36}\text{Ar}$ ($10^{-10} \text{ cm}^3 \text{ g}^{-1}$)

glass. In what follows, $^{40}\text{Ar}_a$ and $^{40}\text{Ar}_m$ denote atmospheric and the unknown mantle ^{40}Ar , while m and a denote their ratios ($^{40}\text{Ar}_m/^{36}\text{Ar}_m$) and ($^{40}\text{Ar}_a/^{36}\text{Ar}_a$) respectively, the former being, of course, unknown. Then¹²

$$\begin{aligned} \left(\frac{^{40}\text{Ar}}{^{36}\text{Ar}} \right)_{\text{measured}} &= \frac{^{40}\text{Ar}_m + ^{40}\text{Ar}_a}{^{36}\text{Ar}_{\text{measured}}} \\ &= \frac{m^{36}\text{Ar}_m + a(^{36}\text{Ar}_{\text{measured}} - ^{36}\text{Ar}_m)}{^{36}\text{Ar}_{\text{measured}}} \\ &= \frac{(m-a)^{36}\text{Ar}_m}{^{36}\text{Ar}_{\text{measured}}} + a \end{aligned} \quad (1)$$

If, therefore, the measured $^{40}\text{Ar}/^{36}\text{Ar}$ plotted against $(^{36}\text{Ar})^{-1}$ gives a straight line for a suite of samples, $(m-a)^{36}\text{Ar}_m$ must be constant for those samples and the concentration and/or isotopic ratio of the trapped component may then be obtainable. Of two early sets of data, one^{1,13,14} gave two reasonably straight lines while the other¹⁵ showed only random scatter. A later set of data from a DSDP core gave an excellent straight-line fit¹⁶. These data are summarized in Fig. 1. Recently Dymond *et al.*¹⁷ combined these data with their own unpublished data and concluded that they show merely random scatter below the upper-limit envelope (Fig. 1a); such behaviour would indicate post-eruptive diffusive loss from the glassy basalts and limit the retrievable information to only a lower limit of the product $(m-a)^{36}\text{Ar}_m$.

It is important to determine whether samples exist which have quantitatively trapped the magmatic Ar without such subsequent diffusive loss, so that reliable estimates of the concentration and isotopic ratio may be determinable in principle and so that the search for vertical and/or lateral differences may be profitably pursued. These data on several determinations of Ar concentrations from one dredge haul, seamount P-50 from the south-east Pacific, (previously described¹) fit the straight-line relationship of equation (1) and thus indicate quantitative retention of the trapped Ar. It is important that this contention refers to the magmatic gases present in the lava as it erupts onto the surface of the Earth. Processes of elemental fractionation¹⁸ or vesiculation¹⁹ preceding eruption might enhance or deplete the elemental concentrations in the glass phase, but would not affect the isotopic ratios.

The data of Table 1 were obtained using a stainless-steel Reynolds-type rare gas mass spectrometer by a process similar to that described in ref. 20. The samples were chips taken from the glass crust of a single basalt flow. Blank levels were $\sim 2 \times 10^{-11} \text{ cm}^3$ for ^{36}Ar ; accuracy, $\pm 10\%$; precision of the $^{40}\text{Ar}/^{36}\text{Ar}$ ratio, $\sim 2\%$. Samples 1, 4 and 7 were heated for 30 s, sufficient to raise the crucible to a red glow, in an attempt to separate the (surface-adsorbed) atmospheric from the internally trapped components. The technique was at least partially successful:

Fig. 1 $(^{40}\text{Ar}/^{36}\text{Ar})_{\text{measured}}$ plotted against $(^{36}\text{Ar})^{-1}$. The data of refs 1, 13 and 14 were measured on glasses from the East Pacific Rise and the Vema Fracture Zone. The solid line shows the slope and extent of samples from a DSDP Cretaceous core taken from the southern end of the Bermuda Rise. ●, Ref. 1; ○, ref. 13; × ref. 14; □, ref. 15.

runs 1 and 4 show only atmospheric Ar, while run 7 contains a small amount of magmatic Ar, identified by the higher $^{40}\text{Ar}/^{36}\text{Ar}$ ratio. None of the samples 1, 4 and 7 would be expected to fall on the 'constant-magmatic' line, as they obviously cannot reflect a constant-magmatic Ar component; indeed, they all lie far off the curve, to the lower right of Fig. 2. As only zero or insignificant amounts of magmatic Ar were removed from the samples in these runs, both the high-temperature fractions and the total abundances should plot along the constant-magmatic line, as, in fact, they do. Samples 10, 11, 18 and 19 are interior rock specimens of P-50; such interior rock are expected not to retain quantitatively the magmatic gases²¹, and indeed these samples lie below the constant-magmatic line.

Figure 2 includes previously published data from this same seamount; the total data bank thus includes measurements on several different samples of this dredge haul, made with three different mass spectrometers at two different laboratories over 12 yr. The straight-line fit to the glass samples (shown in Fig. 2) is remarkably good over the entire range of measurements ($^{40}\text{Ar}/^{36}\text{Ar} = 1,282\text{--}11,300$). Anchored at an intercept of 295,

Fig. 2 The envelopes *a* and *b* are from Fig. 1. Samples 1–11 are from Table 1. Sample 12 is from ref. 14; samples 13 and 14 from ref. 1; samples 15–19 from ref. 13. ●, Glasses, this work; +, glasses, previous work; ○, interior rock; □, first (mild) heating.

corresponding to the model relationship

$$(^{40}\text{Ar}/^{36}\text{Ar})_{\text{measured}} = (m - a) \cdot ^{36}\text{Ar}_m / ^{36}\text{Ar}_{\text{measured}} + a$$

the excellent straight-line fit indicates a constant value for $(m - a) \cdot ^{36}\text{Ar}_m$. In this equation both m and $^{36}\text{Ar}_m$ are unknown. Figure 1 shows that a similar relationship was found by Takaoka and Nagao for DSDP samples from Hole 417D of Leg 51 (Cretaceous basalt flows in the Caribbean¹⁶). They solved equation (1) for m by assuming that either all the ^{36}Ar they measured was trapped magmatic, or alternatively that $^{36}\text{Ar}_m = 5 \times 10^{-10} \text{ cm}^3 \text{ g}^{-1}$ in all the samples. The first assumption provides only an upper limit to $^{36}\text{Ar}_m$; it is obviously an overstatement, as it denies the existence of the constant-magmatic line demonstrated by their data. The second assumption is based on Craig and Lupton's²¹ analysis of the early data^{14,15,22}, which include both atmospheric and magmatic Ar with no attempt to differentiate between the two; the result being no more than an average of all total measured values. This cannot possibly reflect

an accurate world-wide average of the $^{36}\text{Ar}_m$ component alone, as is emphasized by Table 1, in which many of the samples show significantly smaller concentrations of total measured ^{36}Ar . I prefer to rewrite equation (1) as:

$$(^{40}\text{Ar}/^{36}\text{Ar})_{\text{measured}} = \frac{(m - a)}{m} \cdot \frac{^{40}\text{Ar}_m}{^{36}\text{Ar}_{\text{measured}}} + a \quad (2)$$

and then recognize that the maximum measured $^{40}\text{Ar}/^{36}\text{Ar}$ datum is necessarily a lower limit to m , so that from sample 5 $m \geq 11,000$, that is $m \gg a$ and $(m - a) \sim m$. The slope of the line then gives the $^{40}\text{Ar}_m$ concentration directly: $172 \times 10^{-8} \text{ cm}^3 \text{ g}^{-1}$. With $m \geq 11,000$, the concentration of $^{36}\text{Ar}_m \leq 1.5 \times 10^{-10} \text{ cm}^3 \text{ g}^{-1}$.

For the Leg 51 DSDP data the analysis is not as straightforward. We can say that the $^{40}\text{Ar}_m$ must be $\geq 143 \times 10^{-8} \text{ cm}^3 \text{ g}^{-1}$; if the $^{36}\text{Ar}_m \leq 1.5 \times 10^{-10}$, then $m \geq 9,500$. On the other hand, the limit to m set by these data alone is $m \geq 1,700$, and then $^{40}\text{Ar}_m \leq 173 \times 10^{-8} \text{ cm}^3 \text{ g}^{-1}$ and $^{36}\text{Ar}_m \leq 10 \times 10^{-10}$. The mantle component therefore looks similar, but not necessarily identical, to that recorded in the P-50 glass. The similarity in both concentration and isotopic ratio allowed by the data for Ar erupted on the other side of the world and 100 Myr previously is striking.

The data from seamount P-50 show that: (1) Samples do exist which have trapped the magma-ambient rare gas component without post-eruptive diffusive loss. (2) In the region sampled by the P-50 magma, the mantle ratio $^{40}\text{Ar}/^{36}\text{Ar}$ is $\geq 11,000$, more than an order of magnitude higher than several other estimates of the mantle ratio^{4,10,23,24}. (3) Any one measurement of the amount and isotopic ratio of Ar in a given sample is not quantitatively significant, as atmospheric contamination is generally present. Also, unless a straight-line relationship among several samples can be demonstrated, diffusive loss of the mantle component cannot be discounted.

If further measurements show this straight-line relationship in suites of samples erupted from varying depths and geographic positions, and in varying tectonic conditions, we should be able to determine whether or not a reasonably unique worldwide mantle component exists, and thus whether models of atmospheric evolution and terrestrial degassing based on such mantle-wide parameters have a chance of being valid. Alternatively we may be able to document any vertical and/or lateral variations in this component, and thus provide information pertinent to models which require such variations¹⁷.

Samples of P-50 were supplied by E. Bonatti. Research was supported in part by the NSF.

ESR dating of ancient flints

E. G. Garrison* & R. M. Rowlett

Natural radioactivity can produce measurable amounts of radiation damage in rocks and glasses, and the gradual accumulation of this damage with time provides a built in 'clock' that can be used as a dating tool for geology and archaeology. Although a studied technique for estimating this damage involves measurements of stored thermoluminescent (TL) activity¹⁻⁴, several authors have reported the direct observation of natural radiation damage by ESR⁵⁻⁷. We describe here ESR measurements on a damage signal which we have found to be present without exception in a wide variety of natural flints. The point defect responsible for the signal is identified and the samples are calibrated with an artificial damage simulation. Preliminary age determinations are presented for several natural flints. Flint artefacts heated in antiquity will have their clock 'reset' to zero, and measurements on one sample suggest that the ESR technique may have applications in the study of early cultures.

Flint is a hydrothermally grown microcrystalline silica rock. Typical samples contain α quartz, amorphous silica, various silica allomorphs and a few per cent of non-silica 'binder' material. The ESR spectrum generated by natural radioactivity is shown in Fig. 1a. This spectrum is very similar to that found in quartzes artificially damaged by fast neutron bombardment⁸,

damage signal shown in Fig. 1d has two major components; the sharp structure between $g = 2.000$ and $g = 2.0020$ associated with a dangling Si bond (an E' centre), and a broad but well defined, $S = 1/2$, powder pattern at lower field. Ignoring the E', we find the low field signal grows smoothly and uniformly with fast neutron damage, and thermally anneals away as a unit. Pure γ -ray radiation (^{60}Co , up to 3 MR) has little effect on this signal in natural flints. It gives no measurable increment to the natural signal, and in samples where the natural signal has been annealed away, the weak low field signal produced by γ rays has a distinctly different appearance. (An interesting exception is when the natural signal is only partially annealed away, when even a small γ -ray dose will reconstitute a fraction of the original signal before saturating. Presumably, structural precursors are being repopulated here.) An examination of the g values of the natural signal suggests an interpretation for this insensitivity to γ rays. The values agree well with those of the recently identified 'peroxy centre'¹¹, an O_2^- radical bonded at one end to a silicon atom. If we accept this identification, then the defect is an interstitial oxygen, and a displacive lattice collision is needed to produce it.

Whether the structural damage is due to α -recoils or fast neutrons, the ultimate source of point defects is a cascade of displacement collisions in the wake of an energetic (kiloelectron volts) oxygen or silicon ion (a primary knock-on or PKO), and to first order the only parameter required for calibration is the energy deposited in the lattice. For the natural damage this is a straightforward computation. Each emission leads to a recoil nucleus with some 80 keV of energy that ultimately finds its way to the lattice through PKOs. Summing over all decays (^{238}U , ^{232}Th and their daughters in secular equilibrium) leads to an energy deposition rate

$$P_r = 8.12 \times 10^5 (\text{MeV yr}^{-1} \text{ cm}^{-3}) \times C_{\text{eff}} \quad (1)$$

where C_{eff} is the effective radioactive impurity concentration in $\mu\text{g per g}$, given by $C_{\text{eff}} = C_{\text{U}} + 1/3 C_{\text{Th}}$.

Table 1 ESR ages of some geological flints

Sample	Original flint	Accepted geological age (Myr)	t (s)	T	T	P	C_{eff} ($\mu\text{g per g}$)	ESR age (Myr) $\pm 30\%$
				C_{U} ($\mu\text{g per g}$)	C_{Th} ($\mu\text{g per g}$)	C_{U} ($\mu\text{g per g}$)		
3 g	Oklahoma	370	1,507	2.25	3.07	0.26	0.67	310
5 g	Utah	250	1,854	3.00	0.415	0.41	0.70	366
7 g	Africa	3,200(?)	304	0.693	0.802	0.52	0.74	57
9 g	Missouri	320	700	1.11	0.209	0.18	0.29	333
Ill	Illinois	320	1,347	1.20	1.20	0.42	0.664	280

Column 4 gives the average reactor exposure needed to regenerate the native ESR signal, with all data scaled to row 1, site H, reactor conditions. The effective radioactive concentration in column 8 is computed from the measurements of total concentration and powder only concentration in the preceding three columns, as described in the text. The uncertainty quoted in the final column includes statistics and a rough estimate of possible systematic errors.

and also to the native signal observed by McMorris⁵ in igneous (but not in hydrothermal) quartz minerals. We believe, with McMorris, that this signal appears because of structural damage in the silica lattice due to the momentum-conserving nuclear recoils of α -emitting impurities. (β , γ and even α particles dissipate nearly all their energy in electronic processes and do little structural damage.) The signal thermally bleaches at 500 °C (Fig. 1b) and is readily regrown by neutron damage (Fig. 1c).

Recent work on radiation-damaged silica^{9,10} has led to a fairly clear picture of some of the simpler point defects in the silica lattice. The expanded, high-resolution trace of the natural

The total ^{238}U and ^{232}Th concentrations were determined directly by neutron activation analysis. Because flint is heterogeneous, we need to correct these measurements for the fraction of radioactivity in the binder instead of the silica lattice. We estimate this partitioning by crushing the samples and etching them in hot aqua regia. This procedure leaves a fine white powder of silica microcrystals, but removes the binder. ESR of the powder shows that etching removes impurity signals (particularly Mn^{2+}) but leaves the original peroxy signal only slightly reduced. The powder is then re-assayed for ^{238}U and we assume the less important ^{232}Th is distributed the same way. It is probably wrong to neglect the radioactivity in the binder entirely, because some of these atoms will be registered on the crystal interfaces where they can still damage the lattice (the recoil range is $\sim 200 \text{ \AA}$), so we include the binder fraction in our estimates of C_{eff} , but weighted with an efficiency of 0.1.

* Present address: Cultural Resources Laboratory, Texas A & M University, College Station, Texas 77843, USA.

Fig. 1 Absorption derivative ESR signals in Illinois flints. $\nu = 9.1$ GHz, $H_0 = 3,200$ G. *a*, The natural signal, $T = 300$ K. *b*, The same sample after annealing at 773 K. *c*, The same sample after exposure to radiation damage by fast neutrons. Correcting for gain and modulation, the signal is 12 times larger than the natural signal in *a*. *d*, An expanded high-resolution trace near $g = 2$, showing powder pattern turning points near $g_1 = 2.002$ and $g_2 = 2.008$. *e*, A high-gain, high-modulation trace at $T = 100$ K, showing the powder pattern turning point near $g_3 = 2.06$.

To calculate the energy deposited by fast neutrons, the neutron flux distribution must be evaluated at the irradiation site. We have done this by combining reactor-design calculations and measuring thermal neutron fluxes. (In the Missouri University Research Reactor, 27.8 cm from the centre of the core row 1, site H, we find $(d\phi/dE)dE = (k/E)dE$, $E < 3$ MeV, with $K = 4.5 \times 10^{12}$ neutrons per $\text{cm}^2 \text{s}^{-1}$.) These relatively low-energy collisions are nearly isotropic and the total energy given to PKOs is readily computed¹². However, the PKO spectrum has a significant high-energy component, so some of this energy is lost in irrelevant electronic processes. Evaluating this effect with a standard model^{13,14}, we find an overall efficiency of 0.36 for producing structural damage, and an energy deposit rate in the lattice (in row 1, site H of our reactor) of

$$P_n = 1.12 \times 10^{11} \text{ MeV cm}^{-3} \text{ s}^{-1} \quad (2)$$

Combining equations (1) and (2) then leads to

$$\text{Age (Myr)} = 0.139 t(s) / C_{\text{eff}} (\mu\text{g per g}) \quad (3)$$

where t is the reactor exposure time needed to reproduce the native signal.

This last expression was used in a blind study of several old flints. The results are presented in Table 1, along with the accepted geological ages. Except for the Precambrian African sample (an unusual flint subjected to obscure geological processing), the agreement in ages seems very satisfactory.

As expected, flints known to have been heated in the past (by reduced TL) showed a marked reduction in the peroxy signal. One heated sample was investigated more carefully. It came from Combe Grenal France, in an Acheulian archaeological stratum deposited $\sim 2.5 \times 10^5$ yr BP (ref. 15). The ESR spectrum near $g = 2.00$ is contaminated by impurities, but the long plateau

region extending towards $g = 2.06$ (Fig. 1e) shows clear evidence for an elevated absorption when compared with a sample heated in the laboratory. The characteristic peroxy signal reappears after neutron bombardment, and a (lengthy) extrapolation suggests that the reactor exposure time needed to reproduce the original signal would be about 5 s. The total ^{238}U concentration is $2.5 \mu\text{g per g}$, and if this U is partitioned normally between the silica and binder then the maximum elapsed time since heating would be about 5×10^5 yr. Because some of the plateau signal observed could come from centres other than the peroxy, or from an unannealed residue, the heating could well have been more recent. The main refinement needed for dating young samples is not so much an improved signal-to-noise ratio, but rather an ability to discriminate fresh peroxy signal from interfering background. This refinement may prove to be within the capabilities of standard ESR techniques.

The sample from Combe Grenal France was obtained from Professor Francois Bordes.

Stones, pits and Stonehenge

M. W. Pitts

Alexander Keiller Museum, Avebury, Marlborough, Wilts SN8 1RF, UK

There have been many mathematical or astronomical explanations of the construction of certain elements at Stonehenge¹⁻⁹. In 1979 a small salvage excavation at the site resulted in the chance discovery of a prehistoric pit dug to take a standing stone. The recognition that such substantial structures can exist unknown at Stonehenge is important to those who seek alignments or patterns in the locations of neolithic features. That 'known' arrangements could be affected by such unexpected discoveries is here illustrated with a preliminary reassessment of the significance of the Heelstone and the Station Stones (a full description of all aspects of Stonehenge is given in ref. 10).

In May-June 1979, a trench 24×1.5 m was excavated along the proposed route of a telephone exchange cable on the roadside verge (Figs 1, 2). Besides the expected segments of the circular ditch around the Heelstone and the eastern ditch of the Avenue, a completely unexpected prehistoric feature was found. This comprised part of a wide pit with the impression on its base of the stone it had once held upright. No direct dating evidence was obtained, but the pit apparently relates to early activity at the site. The standing stone was removed, and the pit backfilled and fully consolidated before the ditch around the

Fig. 2 Excavation in progress, looking south-east. The stone pit shows as a large depression in the chalk, truncated by the Heelstone ditch which crosses the trench in the foreground. Emerging from unexcavated ground to the right, is the smooth, crushed chalk surface created by the weight of the standing stone. The rectangular excavation at the bottom of the photograph shows the point reached by the Post Office cable when archaeological investigation began. Behind the coils of barbed wire (erected around the site for the period of the summer solstice festivities) can be seen the base of the Heelstone.

Fig. 1 Area around the entrance to the earthwork enclosure at Stonehenge, showing pits (letters), stones (numbers) and the trench excavated in 1979. The newly discovered pit is north of the Heelstone, and the stone impression is shown shaded.

Heelstone was excavated; this ditch had been refilled at the time the ditches and banks defining the Avenue were created, around 2170 BC (BM-1164: 1728 ± 68 b.c., HAR-2013: 1770 ± 70 b.c.; calibrated after Clark¹¹, 2140 ± 150 BC and 2200 ± 155 BC respectively).

The location of this previously unknown stone (called stone 97 in the sequence, after number 96, the Heelstone) questions the relationship of the Heelstone to the site's alignment. The eccentric position of the latter stone to the main axis of the site, which is approximately oriented on the midsummer sunrise has proved puzzling. If stone 97 was standing at the same time as the Heelstone, and the two were erected as part of a single plan, the problem may be solved, for the two stones sit astride the axis. Indeed, Newall predicted the presence of a stone beside the Heelstone on this hypothesis¹². The midsummer Sun would then rise on an alignment, accidentally or deliberately contrived, between the two stones. However, the Heelstone may have been erected after the now missing stone had been removed, with or without a period during which no stone was there at all. This interpretation was favoured by Atkinson (personal communication) who calculated the azimuth of the apparent centre of the impression left by stone 97 from the estimated centre of Stonehenge I as about $48^\circ 21'$. The precise location of the stone could not be determined from the excavated evidence—the stone's shape and size above ground are only definable within very broad limits.

Adopting the hypothesis of the Heelstone as one of a pair of stones, how does this pair fit into the overall arrangement of known stone locations at the site? The distance¹³ both between the main sarsen circle (specifically stones 1 and 30) and the pair of stones at the earthwork entrance (stone 95 and that represented by hole E), and the distance between this last pair and the Heelstone is some 30 m. Can we extend this pattern and interpolate an "imaginarie Walke of stones" similar to those at Avebury¹⁴?

The confused picture presented by antiquarian literature^{15,16} has prompted magnetic and resistivity surveys along part of the Avenue. The results show a strong disturbance in the chalk precisely where the next pair of stones should be, moving on from the Heelstone. The geophysical anomaly indicates the possible presence of only one pit. However, the model would predict this, because for both the known pairs the northwestern stone was removed in prehistory and the pit backfilled with chalk: it cannot be assumed that either of these pits would be visible to sub-surface detecting devices.

The interpretation of the newly discovered stone 97 as a partner for the Heelstone does not, however, exhaust all possibilities; Atkinson has other opinions. An alternative would be that the stone is part of a single row, of which two other stones were identified by Hawley. The now vacant pits (labelled by Atkinson as B and C) and the new pit are equidistantly spaced on a straight alignment. The apparently smaller size of holes B and C, however, suggests that the stones they contained (and note that the existence of these stones is largely hypothetical) did not match the dimensions of 97. Indeed, the new pit is so large, apparently having been sectioned by Atkinson *et al.* in 1956 (ref. 17), that it possibly consists of intersecting pits that fulfill both these suggested roles.

Four outlying features, in addition to the Heelstone, are frequently used in complex geometrical or astronomical constructions. Of these four 'Station Stones', only two survive in position; the others are evidenced by poorly described hollows in the chalk. Their importance lies in their location on the four corners of a perfect rectangle that is aligned on the site's major axis. However, evidence suggests both that the Heelstone and the Station Stones may have had companions, and that the basis of the latter's location was not so much a rectangle as a circle. For this interpretation, we must consider a ring that lies on the periphery of the site.

The 56 more or less regularly spaced pits in this ring were first known as the 'X holes' and later as the 'Aubrey holes'¹⁸, although the association of these 56 pits with the five 'cavities' observed by Aubrey is unconvincing, not least because of the discrepancy in numbers. Note also that these five hollows, supposedly representing the collapsed fill of pits levelled well over four millennia before Aubrey's visit, were apparently

invisible when Gale and Stukely were at Stonehenge less than 60 years later, to Cunnington and Hoare at the end of the eighteenth century, and certainly not to be seen by Hawley or Newall in this century. It therefore seems likely that if the cavities really were prehistoric in origin, whatever they contained had been removed not very long before Aubrey's visit. This being so, they could only have held standing stones.

Atkinson considered the possibility that the Station Stones were the remnants of a former circle, but has preferred to associate them with the large sarsen structure as four outliers, reserving "the bare possibility that they once formed part of an earlier setting of sarsens within the bank"¹⁹. The main evidence for this putative circle consists of three hollows on the site's perimeter—pits F, G and H. As Atkinson and his colleagues noticed, these pits are correctly located to form, together with the Station Stones and 13 hypothetical pits (mostly in unexcavated parts of the site), a circle of perhaps 20 more or less evenly spaced pits, two of which still retain stones, just outside the ring of X holes. A search was made for one of these pits in the 1950s (in the region of X holes 4 and 5) with a variety of sub-surface detecting devices, but nothing was found²⁰. However, it is possible that a pit does exist, but with a chalk fill rendering it effectively invisible without excavation (as would probably have been the case with the newly discovered pit). Hawley considered at least two of these hollows to be natural (one became known as the 'bush hole'), but this appearance could be given by pits with chalky fill exposed by an excavator with very limited knowledge of pedology and the complex geomorphology of the site. Finally, there was circumstantial evidence²¹ that a stone existed on the perimeter of this hypothetical circle near X hole 28.

The cavities which Aubrey observed exhibit both a coincidence in number with the above features, and a remarkable similarity in their respective locations (Fig. 3). The cavities match holes F to H, and Aubrey's two stones the Station Stones 91 and 93. The remaining cavities would correspond to holes now conventionally described as pits for Station Stones 92 and 94. The only major discrepancy lies in Aubrey's relative transposition of stone 93 and the hollow for 'stone' 94. Without further excavation, the existence of this stone circle must clearly remain an open question.

This consideration of the Station Stones and the Aubrey holes, like the description of the newly discovered stone 97, exemplifies an unavoidable, if inconvenient, problem concerning Stonehenge—we really know very little indeed of the nature and sequence of activities and structures at the site.

I thank staff and students of the Department of Archaeology, University of Southampton, and British Telecommunications for cooperation, and Professor Atkinson for interest and unpublished data. The geophysical surveys of the Avenue were conducted by the Department of the Environment's Ancient Monuments Laboratory, who also took plaster and silicone rubber casts of the stone pit bottom. The excavation was funded by the Department of the Environment through the Wessex Archaeological Committee Implementation Fund.

Disappearance of common skate *Raia batis* from Irish Sea

K. Brander

Ministry of Agriculture, Fisheries and Food, Directorate of Fisheries Research, Fisheries Laboratory, Lowestoft, Suffolk NR33 0HT, UK

Records show that the common skate, *Raia batis*, has declined in abundance in the Irish Sea since the early years of the twentieth century, and is now very rare. As I report here, it is possible to calculate the highest mortality which the species will withstand without collapsing. It is likely that the mortality due to fishing has exceeded this level for some time and that the species will not recover while fishing continues. This represents the first clear case of a fish brought to the brink of extinction by commercial fishing.

In 1902 Herdman and Dawson¹ wrote that the common skate, *Raia batis*, was: "abundant in all parts (of the Irish Sea), and taken by line and by trawling all year round on nearly all our fishing grounds. The young are frequently taken in shrimp nets in shallow water". But the records of more than 800 trawl catches made by research vessels of the Ministry of Agriculture, Fisheries and Food (MAFF) throughout the Irish Sea during the past 10 yr show that no specimen of that fish was taken. None has appeared in trawl catches during research cruises by the Marine Science Laboratories, Menai Bridge during the past 15 yr (E. I. S. Rees, personal communication).

Enquiries among fishermen working in all parts of the Irish Sea indicate that *R. batis* was not uncommon in the late 1940s and that a few were taken during the 1950s and early 1960s, but there have been no recent records. In 1960, E. Hardy published a note in *Fishing News* on "The monster skate of Caernarvon Bay", giving details of a 9-foot-long specimen taken in September of that year. The Irish Specimen Fish Committee publishes an annual report, which in 1976 gave details of specimen-sized skate (more than 120 pounds) taken by anglers in Irish waters since 1956. Of those 20 specimen fish, 15 were from Strangford Lough. However, because of the decline in the skate populations, the Committee has suspended the species from its lists since 1976.

The identification of skate and ray species in the commercial landings in England and Wales is incomplete and they are not always recorded separately, however during the past 5 yr an average of less than 10 specimens of *R. batis* from the Irish Sea has been recorded annually at Fleetwood and these have all been from the North Channel. French commercial landings of *R. batis* from the area west of Scotland and Ireland are much higher, but here too the decline has been very rapid. Trawlers from Concarneau landed 922 tonnes of *R. batis* from this area in 1969, but only 85 tonnes in 1979. During the same period the landings of all other species of rays at Concarneau fell by only 15% (M. H. Du Buit, personal communication).

Several aspects of the skate's biology make it particularly difficult to protect from overfishing. Du Buit², commenting on the declining catches by French trawlers in the Celtic Sea, ascribed its vulnerability to slow growth, high age of maturity and low fecundity. Holden³ has modelled the population dynamics of other ray species from the Irish Sea, but did not distinguish between the mortality on immature and mature fish, and thus did not identify the crucial importance of fishing mortality on immature fish in determining the level of exploitation at which the stock would collapse. I have adapted Holden's method and have used his rates of egg laying to calculate the levels of mortality on immature and mature fish beyond which the stock will collapse.

For a population to remain in equilibrium, the mortality rate of mature fish (Z_m) must equal the net rate of recruitment of mature fish. The net recruitment is given by the number of eggs laid per female per year ($E/2$, because only eggs developing into

females are included) multiplied by the survival from egg laying to maturity ($e^{-Z_i t_m}$, if the immature mortality Z_i occurs evenly over the number of years t_m needed to reach maturity).

$$Z_m = (E/2) x e^{-Z_i t_m}.$$

The number of eggs laid per female depends on the size of the female and hence will vary because the average size of mature fish is affected by changing Z_m . For ray species, Holden⁴ has shown that the rate of egg laying is proportional to body length, not weight, so that there will be little change in $E/2$ as Z_m varies. The rate of egg laying by *R. batis* is not known but can be estimated as about 40 per year, using a relationship between fecundity and size at birth⁵. According to Du Buit², the age of first maturity for *R. batis* is 11 yr. The equation thus gives the relationship between Z_m and Z_i shown in Fig. 1. Any combination of values of Z_m and Z_i to the right of curve *a* will result in the collapse of the population. If the population was subject only to instantaneous natural mortality of say 0.2 before maturity, then a very high rate of exploitation would be possible on the mature stock, although this of course assumes that the direct relationship between number of mature females and net recruitment persists at all stock levels, which is unlikely. However, the fishing mortality on immature fish is probably the same as that on mature fish, because they are vulnerable to capture from birth by the same gear.

R. batis hatch from the egg at a length of ~22 cm, with a disk width of 13–15 cm and are retained by the mesh sizes in use. The line expressing the ratio $Z_m = Z_i$ is shown in Fig. 1 and it can be seen that the stock will collapse at a mortality above ~0.37. Even if the immature mortality were only half of the mature rate (that is $Z_m = 2 \times Z_i$, also shown in Fig. 1) the stock would still collapse when Z_i was 0.31. In fact, the immature mortality may well be higher than the mature mortality, because in addition to being caught in the same gear as the mature fish, the young skate were also taken frequently in shrimp nets in shallow water. Also, no account has been taken of egg and hatching mortality, which may be high and will act in a manner exactly analogous to reduced fecundity. Curve *b* in Fig. 1 expresses either 50% egg mortality or fecundity of only 10 female eggs per year instead of 20. This shows that reduced (or increased) fecundity has a relatively small effect on the mortality at which the stock collapses. It is the net rate of recruitment which is important, and this is determined largely by the cumulative mortality during the immature stage.

No estimates of mortality rates are available for the ray species of the Irish Sea, but they are likely to be of the same order as those on other demersal species, which range from ~0.4

Fig. 1 Values of Z_m (mortality rate on mature fish) and Z_i (mortality rate on immature fish) to maintain the population in equilibrium. *a*, Fecundity = 20♀ eggs per yr; *b*, fecundity = 10♀ eggs per yr.

Fig. 2 Value of total mortality ($Z_i = Z_m$) beyond which the population will collapse, for different values of fecundity and age of maturity.

to 1.2 (total instantaneous rates on an annual basis⁶). The disappearance of *R. batis* is therefore not surprising, but that this took place virtually unnoticed or without comment in the fisheries literature, perhaps is surprising. Other ray species have also declined⁶, but are less vulnerable, as can be seen from Fig. 2. This shows the highest total mortality which the different species could withstand without collapsing, as a function of fecundity and age of maturity. It is assumed that $Z_m = Z_i$, but young *R. clavata*, *R. brachyura* and *R. montagui* may be less vulnerable to fishing mortality than *R. batis*, as they are smaller.

The prediction from Fig. 2 that *R. erinacea* would withstand the highest mortality of any of these species, in spite of having the lowest fecundity, emphasizes that net survival to maturity rather than fecundity *per se* governs the response to exploitation. For *R. batis* the only effective protection is probably a complete halt to all kinds of fishery in which it may be caught. Because this course of action is unrealistic, it has to be accepted that this species and others like it will be fished out as a consequence of the exploitation of other demersal fish.

Infant-related influences on birth intervals in rhesus monkeys

M. J. A. Simpson, A. E. Simpson,
J. Hooley & M. Zunz

MRC Unit on the Development and Integration of Behaviour,
University Sub-Department of Animal Behaviour, Madingley,
Cambridge CB3 8AA, UK

That a mother's relationship with her infant could influence her subsequent reproductive history can be argued as follows. A rhesus monkey infant whose next sibling is to be born in a succeeding birth season¹ could compete with it by trying to postpone the date when its mother next conceives. If the mother preferred a shorter delay than the infant², processes of conflict³ and negotiation⁴ involving the two could show in some of the behavioural interactions constituting their relationship⁵. For example, a mother could try to hasten the onset of her next pregnancy by trying to promote more independent behaviour in her infant, perhaps by rejecting some of its bids for contact^{3,4}. We report here studies on our rhesus monkey colony and other colonies which support this argument.

We compared two reproductive groups of mothers in our colony¹: 'quick' mothers, who have an infant in the present birth season¹ and will conceive another in the coming mating season, with 'slow' mothers, who bear an infant this season but will not conceive another in the coming mating season. The two groups differed as follows: current infants of quick mothers included a higher proportion of males than did current infants of slow mothers (Fig. 1, $P < 0.01$ by Median test⁶, excluding two sons and four daughters whose mothers have not yet produced another full-term infant); current infants of quick mothers were more active, crossing grid lines in their cages more often⁷ during their first 12 weeks ($P = 0.048$, 0.008 and 0.035 in weeks 2, 4 and 8 respectively, Mann Whitney U-test); and quick mothers rejected^{7,8} their infants more often in seven of the eight observation weeks up to week 20 (Fig. 2, $P < 0.10$ in weeks 2-10, $P < 0.018$ in week 6 and < 0.011 in week 10).

In Bernstein's captive colony of rhesus monkeys⁹, more mothers of sons than of daughters were 'quick' (personal communication). Colvin (personal communication) found the same in the free-ranging rhesus population on Cayo Santiago in 1978-79 ($P = 0.0072$, Fisher exact probability test), but it has not been found in free-ranging populations studied over longer periods, either on Cayo Santiago (ref. 10, and Sade and Berman, personal communication) or on La Parguera (Leighton-Shapiro, personal communication). At this stage we presume that the special conditions in captive colonies of rhesus monkeys, and in

Fig. 1 Ages in weeks of current sons and daughters when their mothers conceive infants to be born in the next birth season (quick), and numbers of sons and daughters whose mothers fail to give birth in the next season (slow). The conception date of each infant to be born next season was calculated by subtracting 168 days²⁶ from its birthdate. The 43 infants and their mothers were healthy through at least the year following the births of the current infants, and those births occurring in the next season were full term¹. Our rhesus monkey colony has six separately caged groups, each with one adult male, 2-5 adult females, and immature individuals which have been born into the group¹.

some years in free-ranging populations, determine that an infant's sex becomes associated with its mother's next conception date.

In our colony, the tendency of mothers of males to conceive sooner could be explained in terms of infant activity level, if male infants as a group are more active. We found this to be the case in the infants' second week when more sons than daughters entered at least one new cage section during 6 h of observation ($P = 0.023$, Fisher exact probability test). Thereafter entry rates into new cage sections no longer differentiated male and female infants, but in all observation weeks during their first half year, males initiated more of the play episodes in which they were involved (see also ref. 11). (After week 2, when all infants can move freely, we do not expect males to enter more cage sections than females, because male social play often includes much rough-and-tumble activity in one place, whereas female play may include more chasing to and fro¹¹.)

If infant activity is associated with subsequent maternal conception date, this association should also show within the infant sex classes separately. Taking sons alone, those with quick mothers were more active in weeks 2, 4 and 6. Daughters with quick mothers were more active in all 10 observation weeks up to week 28 ($P < 0.022$ in weeks 8, 10, 16 and 20 by Mann Whitney U-test). Also, in all these weeks, daughters of quick mothers spent less time on their mothers' nipples ($P < 0.05$ in week 20, Mann Whitney U-test). If an infant's sucking behaviour is related to other aspects of its activity, one mechanism promoting early conception could involve sucking¹²⁻¹⁴ (at least in our mother-daughter dyads).

The association between maternal rejection scores^{7,8,15} and subsequent conception held true for sons and daughters separately throughout their first 10 weeks (Fig. 2), quick mothers being more rejecting. In a group of savannah baboons, less restrictive mothers had a shorter postpartum amenorrhea, although they did not conceive again sooner¹⁶. Baboon mothers who were less restrictive were also more rejecting^{4,17}. Associations between a mother's social position in her group and her fertility are also to be expected, and occur for our mothers of males (work in progress).

We provisionally suggest the following mechanism to explain why mothers who reject their infants should be more likely to conceive relatively early. A mother both responds to and tests the progress of her infant, conceiving earlier, the better its progress seems to be². That mothers could be affected by their infants' activity is suggested by the correlation between infant activity and maternal rejection rate in the infants' early weeks (Spearman rank-order correlation coefficient = 0.65, 0.80, 0.49 and 0.43 in weeks 2, 4, 6 and 8 respectively, $P < 0.007$). Mothers could even test their infants' capacity for activity by persisting in their rejecting behaviour until the infants begin to protest. The view of progress so acquired by the mother should be quite reliable, for by falsifying it² the infant could act to its own disadvantage. A clinging and sluggish infant would miss opportunities for play and exploration¹⁸.

This hypothesis does not explain why more mothers with male infants should subsequently be quick to conceive, unless we accept the greater activity of the sons at 2 weeks as a sufficient explanation. However, one or more of the following infant sex differences, expressed *in utero* and later, could also be effective. Thus our rhesus mothers pregnant with male fetuses received fewer threats, chases and attacks than those pregnant with females (work in progress), and pigtail macaque mothers (*Macaca nemestrina*) carrying male fetuses were less likely to require medical treatment (usually for bite wounds from social companions) than those carrying females¹⁹. Chamove's stump-tail macaques (*M. arctoides*), whose infants were removed at birth, bore subsequent infants sooner if they were male (personal communication). Rhesus mothers caged singly with their infants²⁰, and in our social groups (work in progress) played more often with male than with female infants, and male infants initiated a greater proportion of their play sessions than females¹¹.

Fig. 2 Maternal rejection of daughters and sons through the infants' first 16 weeks, depending on whether mothers will conceive again between the infants' 16th and 52nd weeks (quick: ●, daughters; ▲, sons), or later (slow: ○, daughters; △, sons). Each data point is a median frequency of rejection from 6 h of observation¹⁵ of one of the groups. A rejection^{7,8,15} was scored each time a mother hit, pushed or bit her infant, blocked its access to her ventrum and/or nipple, or broke contact with it within 5 s of the infant initiating a period of physical contact with her. A rejection was also scored when the infant was already in contact with the mother's body and she blocked its access to her ventrum and/or nipple. The 43 infants were born to 20 mothers over a 7-yr period, and were treated as if they were statistically independent⁶. This is justifiable because we found that none of our six social groups, nor any of our families within social groups consistently produced infants that were male rather than female, or quick rather than slow.

The idea that mothers in good condition should produce sons rather than daughters²¹ suggests another explanation of our results. If old mothers were in poor condition and therefore 'slow', maternal condition could explain our observation that mothers of daughters tended to be slow. But many of our old mothers were vigorously maintaining high dominance status in their social groups, and were as quick or slow according to the sex of their infants as the remainder of our mothers.

High maternal rank could be the common factor underlying a tendency to have daughters⁴ and then to be slow. However, our high-ranking mothers of sons were among our 'quickest' mothers of all (work in progress).

The survival value to mother, and infant, of the mother being able to respond to and test her infant's progress is easily seen. It is less obvious, in terms of evolutionary theories, about how parents should invest care in their current and future offspring^{2,21-24}, why mothers of male rhesus infants, which are the slightly heavier sex at birth, should conceive again sooner. (Males are heavier in all studies known to us, but only statistically significant in that of Goy, personal communication.) In red deer (*Cervus elaphus*) the heavier stag calves are believed to be more costly to rear and in accordance with this idea their mothers are more likely to have a subsequent barren year²⁵. We wish to note the contrast provided by our rhesus monkeys and make a plea for comparable studies of more species.

The MRC supported the writing of this letter. The monkey colony was supported initially by the Mental Health Fund, and continuously by the MRC and the RS.

Hepatitis B polypeptide vaccine preparation in micelle form

Jacinta Skelly, C. R. Howard & A. J. Zuckerman

WHO Collaborating Centre for Reference and Research on Viral Hepatitis, Department of Medical Microbiology, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E 7HT, UK

The immunoprophylaxis of hepatitis B is hampered by the lack of a technique for growing hepatitis B virus (HBV) in tissue culture. Plasma from persistently infected individuals¹, one source of viral antigen, contains characteristic 22-nm spherical particles which share a common antigen (the hepatitis B surface antigen or HBsAg) with the outer envelope of the 42-nm double-shelled DNA virus. Highly purified inactivated 22-nm particles have been shown to be safe and to confer protective immunity against HBV in a recent large-scale clinical trial². We have already described the extraction from the particles of a complex of two proteins which are antigenic determinants of HBV—the polypeptide with molecular weight (MW) between 22,000 and 24,000 (called p23) and the glycosylated polypeptide (called gp28) with MW in the range 26,000-29,000 which is thought to be the glycosylated form of p23. We now report the preparation from this complex of water-soluble protein micelles which may be a suitable basis for a second-generation hepatitis B vaccine.

In the preparation of viral vaccines, highly purified viral antigens may be significantly safer than other preparations. Many viral vaccines contain not only specific viral antigens but also components derived from the host tissues in which virus has been grown and against which those to whom the vaccine is administered may react. The availability of a chemically defined polypeptide viral antigen may be especially important for HBV, for there are several reports of the persistent presence in preparations of 22-nm spherical particles of host-serum proteins^{3,4} which may inhibit the immune response or even induce immunological side reactions⁵. Sources of HBV antigen such as the hepatoma cell line PLC/PRF/5 (ref. 6) and *Escherichia coli* containing cloned viral DNA (ref. 7) are similarly contaminated. The advantages of vaccines based on pure antigens have, however, been demonstrated with influenza, where a vaccine consisting of the neuraminidase and haemagglutinin subunits has been shown to be adequately immunogenic when given in two doses and less stimulating of side reactions than the whole virus vaccine.

In our search for a chemically characterized antigen of HBV, we have concentrated on the surface antigen (HBsAg) present in

the 22-nm particles in plasma, which consist of lipid and several viral and host proteins (including, for example, serum albumin^{8,9}). The two peptides p23 and gp28 (refs 8, 10), which form a 49,000-MW complex in non-reducing conditions¹¹, have identical amino acid sequences at the N-terminal end¹² and recent nucleotide sequences¹³ suggest that there is an internal sequence of 19 hydrophobic amino acids which may be the site of the intercalation of the proteins in the 22-nm particles. It seems reasonable, therefore, to consider gp28 and p23 as integral membrane proteins, by definition partially hydrophobic and insoluble in aqueous media in the absence of detergents¹⁴. Complete solubilization of the integral proteins of viral membranes, with minimal loss of serological activity, has been most successfully achieved by the use of non-ionic detergents such as Triton X-100^{15,16}. However, the polypeptides are poor immunogens in a monomeric form in detergent solutions¹⁷. Recently, a method of detergent removal has been described which allows the amphiphilic proteins to reassociate through their hydrophobic portions into a protein micelle structure, which remains water soluble due to the presence on its outer surface of the hydrophilic portions of the molecules¹⁸.

Micelles prepared from Semliki Forest virus membrane proteins were highly effective in inducing a protective response to the virus in mice¹⁷. Applying this type of strategy to 22-nm HBsAg spheres purified from the serum of a carrier chimpanzee, we have previously reported the extraction of a complex of gp28 and p23 by Triton X-100 solubilization and affinity chromatography⁸. The 3.9S complex of p23 and gp28 was prepared essentially according to this method⁸. Purified 22-nm spheres, labelled with ¹²⁵I, were disrupted with 2% Triton X-100. The complex was separated from other particle constituents by

Fig. 1 Sedimentation of solubilized p23 and gp28 in 20-50% linear sucrose gradients in the absence (●) or presence (○) of 2% Triton X-100 throughout the gradient. The 22-nm HBsAg particles were purified from the serum of a persistently infected chimpanzee and radiolabelled with the Bolton and Hunter reagent, as previously described²². ¹²⁵I-HBsAg in 0.01 M Tris buffer was made 2% with Triton X-100 and 0.5 M with NaCl, and incubated overnight at 37 °C (ref. 8). The solubilized material was passed through a column of Con A-Sepharose equilibrated in the complete reaction buffer supplemented with 1 mM CaCl₂ and MnCl₂. The gp28-p23 complex was eluted with α -methyl mannoside and layered directly onto 20-50% linear gradients of sucrose in TNE buffer (0.50 M Tris-HCl, pH 7.4, 0.14 M NaCl, 0.001 M EDTA). After centrifugation at 220,000g for 24 h at 15 °C in a Beckman SW40 rotor, 0.5-ml fractions were collected from the top of the tube and counted to locate the position of the polypeptides. The direction of sedimentation is from left to right.

Fig. 2 *a*, Electron micrograph of HBsAg micelles negatively stained with 1% ammonium molybdate, containing 0.1% bacitracin. The micelles were freed from sucrose by passage through a small column of Sephadex G-25 (Pharmacia) equilibrated with distilled water, and applied to carbon-formvar-coated copper grids. After staining, the grids were examined in a Jeol CX100 electron microscope operated at 80 kV. Scale bar, 100 nm. *b*, SDS-polyacrylamide gel electrophoresis of HBsAg micelles. 40 μ g were disrupted by heating for 2 min at 100 °C or in the presence of 2% SDS and 5% 2-mercaptoethanol, and electrophoresed through a 10% acrylamide cylindrical gel at a constant current of 2.5 mA.

Fig. 3 Competitive radioimmunoprecipitation assay of HBsAg micelles (●) and intact 22-nm particles (○). Both samples were adjusted to 360 μ g ml⁻¹ of protein and serially diluted fourfold in phosphate-buffered saline (PBS) containing 0.5% of bovine serum albumin (BSA). A 150- μ l aliquot of each dilution was mixed with an equal volume of a 1:100 dilution of rabbit hepatitis B surface antibody (anti-HBs) (Hoechst) and incubated at 37 °C for 3 h. ¹²⁵I-HBsAg (intact 22-nm particles, 10 μ l, 24,000 c.p.m.) was then added and incubation was continued overnight at room temperature. A 150- μ l aliquot of protein A-Sepharose (Pharmacia) at a concentration of 5% in PBS-BSA was then added and the samples were shaken vigorously for 1 h at room temperature. The Sepharose was pelleted by low-speed centrifugation and the supernatants and pellets separated and counted. The results are expressed as the percentage of total counts associated with the precipitated immune complexes.

affinity chromatography on concanavalin A (Con A)-Sepharose in the presence of the detergent, and retained specific reactivity with anti-HBs after elution with α -methyl mannoside. The complex in detergent solution was then centrifuged into two 20–50% w/v sucrose gradients, one of which contained 2% Triton X-100 throughout (Fig. 1). In the gradient containing detergent, all the radioactivity remained at the top; in the absence of detergent a peak of ¹²⁵I-labelled protein was found two-thirds of the way down the gradient¹⁸. These results indicated that sedimentation of the complex into a detergent-free gradient separated the polypeptides from the detergent and allowed them to reassociate during centrifugation into a particulate protein micelle form with an increased sedimentation coefficient.

The buoyant density of the micelles in caesium chloride was 1.25 g ml⁻¹ compared with a density of 1.19 g ml⁻¹ for intact 22-nm particles, an increase consistent with the removal of most of the lipid by the solubilization procedure. Electron microscopy showed that the micelles were pleomorphic and fluffy in appearance, with diameters in the range of 60–200 nm (mean 120 nm) (Fig. 2a). Immune electron microscopy showed that the micelles could be both self-aggregated and co-aggregated with intact 22-nm particles by anti-HBs¹⁹. Polyacrylamide gel electrophoresis (Fig. 2b) showed that both gp28 and p23 were present in the same proportions as in the original detergent extract, indicating that the micelles were not formed preferentially from one or other polypeptide. Although the possibility that each polypeptide might have segregated into different micelles was not examined, it seems unlikely in view of the recent demonstration of a disulphide linkage between them¹¹. Gp28 and p23 together constituted 40% of the total protein of the purified 22-nm particles used as starting material in these experiments (see ref. 8). Ninety per cent of the gp28–p23 complex was recovered from the Con A-Sepharose column, and the final yield of the two polypeptides in micelle form was estimated to be 60–70% of the amount originally present in the intact 22-nm particles. The good recovery of total protein confirms the suitability of the method for large-scale production of a potential vaccine.

The degree of antigenic reactivity and specificity of the micelles was assessed by subjecting them to competition with

intact HBsAg particles for anti-HBs in a radioimmuno-precipitation test (Fig. 3). The micelles competed effectively with intact 22-nm forms, although the dilution curve had a slightly shallower slope than that obtained in a control experiment using unlabelled intact 22-nm particles as the competing antigen. Such a difference, indicative of altered protein conformation, was to be expected following removal of lipid and reassociation of the polypeptides into a purely protein form. It is difficult to give a precise estimate for the recovery of serological activity due to the difference in slope, but the competitive ability of the micelles was about 40% that of the intact 22-nm particle per weight of protein. The differences in surface area, and in surface distribution of antigenic sites between the two types of particles, may account for this discrepancy.

The immunogenicity of the micelles was compared with that of intact 22-nm particles in a mouse potency test, as it has been suggested that the serological response in mice may be a useful indicator of the immunogenic potential of candidate hepatitis B vaccines²⁰. Groups of six SWR/J mice were inoculated with three serial doses of 5, 10 or 20 μ g of each preparation in alum-adsorbed form, and the antibody levels in their sera measured by a protein A radioimmunoassay. The results obtained are shown in Fig. 4 in two forms. Figure 4a is a plot of the mean values of the serial dilutions of all sera obtained from mice inoculated with 10- μ g doses of micelles or intact particles.

Fig. 4 Potency testing of HBsAg micelles and 22-nm particles. Both types of preparation were dialysed into 0.01 M phosphate buffer, pH 6.6, and adjusted to a final concentration of 200 μ g of protein per ml. A 1-ml aliquot of a 2% suspension of aluminium phosphate was added to 6 ml of each sample and the protein adsorbed to the gel by mixing the suspensions for 3 h. The alum was then centrifuged and washed once with PBS. Over 95% of the antigen was adsorbed by the alum. The alum was resuspended in PBS to a final concentration of 0.4%. The suspensions were then diluted appropriately with 0.4% alum in PBS so that both the volume and alum content of the inocula were the same for all antigen doses. Six mice per dose were injected intraperitoneally with 20, 10 or 5 μ g of either the intact 22-nm particle or the micelles in 100- μ l volumes. Two booster doses were given at weekly intervals. The mice were bled 11 days after the last inoculation and the titres of anti-HBs determined using a protein A radioimmunoassay. Flexible microtitre plates (Dynatech) were coated with 100 μ l per well of HBsAg at a concentration of 10 μ g ml⁻¹ in carbonate buffer, pH 9.5, by overnight incubation at 4 °C. The antigen was removed and 100 μ l per well of fetal calf serum added to block any remaining adsorption sites. After 2 h at 4 °C, the fetal calf serum was removed and the plates washed with PBS. 100- μ l aliquots of serial twofold dilutions of the test serum in PBS-BSA were incubated in the plate for 2 h at 37 °C, the wells were drained and rinsed and 100 μ l of ^{125}I -protein A was added to each. After 1 h at 37 °C, the plate was drained, washed several times with PBS and divided into individual wells for counting in a γ spectrometer. Protein A (Pharmacia) was iodinated by the chloramine-T method to a specific activity of 20–40 μ Ci μ g⁻¹. *a*, Protein A radioimmunoassay of anti-HBs in the sera of mice inoculated with 10- μ g doses of either micelles (●) or intact 22-nm particles (○). The sera were initially diluted 1:10 in PBS–0.5% BSA. The points represent the mean of six sera, and the vertical lines represent the standard deviations. *b*, Geometric mean antibody titres at different dose levels of HBsAg micelles (●) or 22-nm particles (○). Titres are expressed as the reciprocal of the dilution of antibody required to bind a given amount of radioactive protein A. Each point represents the titre in a single animal. The antigen extinction doses in each case are indicated.

Consistently higher levels of anti-HBs were induced in animals receiving micelles, possibly also with a higher affinity, as indicated by the steeper slope of the dilution curve compared with that of the sera from mice receiving intact particles, although direct affinity measurements were not made. This difference was seen at all dose levels tested. Figure 4b shows the antibody titres against dose for all animals, each point representing the titre of an individual serum. Extrapolation of the lines representing geometric mean titres of antibody gave antigen extinction values of 1.11 μ g and 3.16 μ g for HBsAg micelles and intact particles, respectively. Several factors may, singly or in combination, account for the greater immunogenicity of the micelles, including their large size, altered distribution of antigenic sites, and the absence in them of host-derived serum proteins such as albumin. The results presented here show that the antigenic complex of gp28 and p23 can be readily isolated in high yield from intact HBsAg 22-nm particles, and that this complex can be reassociated into a micellar form as has been described for other viral envelope proteins^{18,21}. The chemical purity, specific serological activity and powerful immunogenicity of the micelles, taken together with the ease of their preparation on a large scale, strongly favour their development as an alternative second-generation hepatitis B vaccine. This physical form may indeed also be suitable for vaccines prepared using HBsAg polypeptides produced by the expression of cloned hepatitis B virus DNA in *E. coli* or other hosts⁷. Experiments to test the immunogenicity, safety and protective capacity of HBsAg micelles in primates are in progress.

We thank Mr M. Vaudin and Miss R. Smith for technical assistance, and Dr D. Ellis for aid and advice with electron microscopy. The programme of hepatitis B vaccine research at the London School of Hygiene and Tropical Medicine is

supported by the Wellcome Trust, and in part by the Department of Health and Social Security and Organon BV, Oss, Holland.

Ethyl β -carboline carboxylate lowers seizure threshold and antagonizes flurazepam-induced sedation in rats

P. J. Cowen, A. R. Green & D. J. Nutt

The mammalian central nervous system possesses specific high-affinity binding sites for the benzodiazepines and considerable evidence suggests that these binding sites are the pharmacological receptors through which these compounds act^{1–6}. Recently⁷, ethyl β -carboline-3-carboxylate (β -CCE) has been identified in both human urine and rat brain. β -CCE may be closely related to the endogenous ligand for the benzodiazepine receptor—it shows an affinity for the receptor of the same order as that of clonazepam, one of the most potent benzodiazepines, and is the first non-diazepinoid structure to be identified with an affinity in the nanomolar range. Furthermore, it is selective for the benzodiazepine receptor⁷. Clinically and in animal studies, benzodiazepines have anti-convulsant, hypnotic and anxiolytic actions⁸. We have therefore investigated whether β -CCE exhibits any of these properties in rats. We report here that, in contrast to the benzodiazepines, β -CCE lowers seizure threshold and reverses the sedative effect of flurazepam. If β -CCE has a close structural relationship to the endogenous ligand, benzodiazepines may be antagonistic at the receptor site.

β -CCE was synthesized by condensation of L-tryptophan with glyoxylic acid, esterification of the product with ethanol-HCl and oxidation with chloranil. The purity of the final product was >95%.

The effect of β -CCE on seizure threshold in rats was determined by measuring the dose of bicuculline, infused through a tail vein, required to elicit a seizure⁹. The β -CCE was dis-

Fig. 1 Effect of β -CCE on the seizure threshold to bicuculline at various times following administration. Results show the seizure threshold for a group of un.injected rats (▲) and for groups of vehicle-injected (●) and β -CCE (5 mg per kg)-injected (■) animals. Results show mean $\pm$ s.e.m. for groups of four or more rats. The β -CCE group was significantly different from the vehicle-injected group— $P < 0.001$ at 5 min and $P < 0.005$ at 15 min.

solved in ethanol, diluted with propylene glycol (ethanol/propylene glycol, 1:2) and injected intravenously (i.v.). Control rats received the vehicle alone. Each rat was only used once for any determination.

When β -CCE was given i.v. at a dose of 5 mg per kg, there was a significant (31%) decrease in the dose of bicuculline required to elicit a seizure 5 min later. Only a small lowering of threshold was seen 15 min after administration and no effect was observed after 30 min (Fig. 1).

Pretreatment of rats with a dose of β -CCE as low as 0.5 mg per kg i.v. had a statistically significant effect in lowering seizure threshold 5 min later and the drug displayed a conventional log dose-response curve (Fig. 2). The effect of β -CCE on lowering seizure threshold plateaued at about 2.5 mg per kg, suggesting that the compound itself will not induce convulsions even at high doses.

When β -CCE (5 mg per kg) was given intraperitoneally, no effect on the bicuculline seizure threshold was seen 5 min later (vehicle 0.28 ± 0.02 mg per kg, $n = 4$; β -CCE 0.32 ± 0.04 mg per kg, $n = 4$). This could be due to rapid inactivation and may explain the short duration of action of the drug even when given i.v.

Benzodiazepine receptors are thought to be functionally linked to γ -aminobutyric acid (GABA) receptors^{10,11} and bicuculline is a GABA receptor antagonist¹². We therefore examined the effect of β -CCE on the seizure threshold using pentylenetetrazol (PTZ), as this convulsant agent also has GABA-antagonist properties¹³. We also investigated the effect on β -CCE on the seizure response to strychnine, a glycine antagonist, to see whether the action of β -CCE was specific to drugs acting on GABA functions. Five minutes after administration of β -CCE at a dose of either 5 or 1 mg per kg the seizure threshold to PTZ was lowered by a value (30%) comparable with that seen using bicuculline (vehicle 23 ± 3 (5); β -CCE (5 mg per kg) 16 ± 3 (6); β -CCE (1 mg per kg) 15 ± 3 (4), expressed as dose of PTZ (mg per kg) to elicit a seizure; β -CCE different from vehicle, $P < 0.001$, at both doses).

In contrast, no change was seen in the strychnine seizure threshold (vehicle 2.7 ± 0.2 (4); β -CCE (5 mg per kg) 2.7 ± 0.1 (4), expressed as dose of strychnine (mg per kg) required to elicit seizure). Following flurazepam (10 mg per kg) the PTZ seizure threshold is raised whereas the strychnine threshold is unaltered¹⁴.

When rats were given flurazepam (20 mg per kg intraperitoneally) they rapidly showed sedation and, in contrast to control animals, displayed very little 'exploratory' locomotor activity when placed in a new cage. This was reflected in low counts on Automex activity meters (Fig. 3). Injection of vehicle had no significant effect on this low level of activity. In contrast,

Fig. 2 Effect of dose of β -CCE on bicuculline-induced seizure threshold. Main graph shows dose of bicuculline required to elicit seizure 5 min after injection of various doses of β -CCE. All doses of drug were given in the same volume of vehicle (1 ml per kg). Zero value shows threshold following vehicle alone, which is not different from a saline-injected group (0.26 ± 0.01 , $n=4$). Different from vehicle control: 10, 5 and 2.5 mg per kg, $P < 0.001$; 1 mg per kg, $P < 0.01$; 0.5 mg per kg, $P < 0.02$; not significantly different: 0.1 mg per kg; four or more observations at each point. Inset shows the log dose-response curve of β -CCE measured against the mean percentage decrease in seizure threshold.

β -CCE (5 mg per kg i.v.) administration partially reversed the sedative effect of the flurazepam for about 10 min after injection (Fig. 3). β -CCE (5 mg per kg i.v.) alone did not produce an increase in locomotor activity compared with rats given vehicle. This suggests, therefore, that the increase in activity in flurazepam-treated rats receiving β -CCE resulted from an antagonism of the sedative effect of flurazepam.

There have been extensive investigations of the biochemical and behavioural effects of both natural and synthetic β -carbolines, some of which have been shown to have convulsant or anticonvulsant properties^{15,16}. However, of the several β -carbolines studied by Braestrup *et al.*⁷, only β -CCE and methyl β -carboline-3-carboxylate showed high-affinity binding (comparable with diazepam) to the benzodiazepine receptor. Although, as these authors admit, it is unlikely that β -CCE is the endogenous ligand, the ethyl ester group having been added during the isolation and purification process, they nevertheless suggest that it may be closely related to the endogenous ligand^{7,17}.

Sieghart and Karobath¹⁸ have recently demonstrated a heterogeneity of benzodiazepine receptors separable, after photoaffinity labelling, by SDS-polyacrylamide gel electrophoresis into two major bands with apparent molecular weights

Fig. 3 The activity response of rats placed in cages on Automex activity meters following pretreatment with flurazepam (20 mg per kg, $n=4$, $\square$), flurazepam plus vehicle ($n=6$, $\blacksquare$), flurazepam plus β -CCE (5 mg per kg i.v., $n=7$, $\bullet$) or saline ($n=4$, $\circ$). Saline or flurazepam were given 15 min before the β -CCE or vehicle. Results show activity measured in recorded counts per min against time (min) after β -CCE or vehicle. Results at 2 min show response in the period 1–2 min post-injection. Flurazepam plus β -CCE is significantly different from flurazepam plus vehicle group at $P < 0.05$ or better for the points 2–10 min inclusive. Flurazepam plus vehicle was at no time significantly different from flurazepam alone.

of 51,000 (P_{51}) and 55,000 (P_{55}). The receptor subpopulations show a differential regional distribution, the cerebellum containing mainly P_{51} and the hippocampus approximately equal amounts of P_{51} and P_{55} . Data¹⁹ showing a lower IC_{50} for β -CCE in the cerebellum than hippocampus, indicates a greater affinity of β -CCE for the P_{51} than the P_{55} -subtype, but this difference in affinity is probably less than one order of magnitude. Such a small difference prevents a detailed interpretation of experiments, such as those reported here, performed on two different behavioural paradigms. We can conclude that the β -CCE has effects opposed to the benzodiazepines, but not that the reversal of the flurazepam-induced sedation and the convulsant effects of β -CCE are mediated through the same subpopulation of benzodiazepine receptors.

Peripheral nerve grafts in hereditary leukodystrophic mutant mice (twitcher)

F. Scaravilli & Jean M. Jacobs

Department of Neuropathology, Institute of Neurology,
The National Hospital, Queen Square, London WC1N 3BG, UK

The twitcher mouse is a mutant affected by a form of leukodystrophy which shows close similarities to human globoid cell (Krabbe's) leukodystrophy. Transmission is by an autosomal recessive gene *twi*. Progressive loss of myelin sheaths from both central and peripheral nervous systems and the presence of inclusion-laden macrophages are characteristic findings. Morphological features of the twitcher have been described by Duchen *et al.*¹. Nerve iso- and allografting have been used to determine the roles of axon and Schwann cell in a number of mouse² and human³ nerve abnormalities. Schwann cells in a graft proliferate and become associated with regenerating host axons which grow through the graft into the host distal stump. In the twitcher, peripheral nerve axons do not degenerate but are thinner than normal, although there is considerable axonal degeneration in the central nervous system. In 15-day-old mutants, inclusions have been found in Schwann cells associated with apparently normal myelin sheaths. Grafting experiments might show whether the phenotype of this mutant is fully expressed in the Schwann cell, or if axons are also involved. In previous experiments, survival of transplanted Schwann cells was achieved by the use of T cell-suppressed^{2,3} or nude mice⁴. We report here that a twitcher nerve transplanted in immunologically unsuppressed animals reproduces all the characteristic features of leukodystrophy and conversely that Schwann cells from unaffected mice can produce normal myelin when associated with twitcher axons.

Myelin seems to form normally until the mice are ~15 days old although the myelin sheaths and axons are rather thinner than those of normal littermates. Later, the myelin sheaths start to degenerate and macrophages containing inclusions appear. By 3–4 weeks, peripheral nerves are macroscopically swollen; many axons are demyelinating or bare of myelin and others have thin myelin sheaths indicative of remyelination; the fibres are widely separated by endoneurial fluid and by large numbers of macrophages. There are various inclusions in macrophages and Schwann cells—those of particular interest are the multi-angular bodies and twisted tubules (Fig. 1a, b) also found in the human⁵ and canine⁶ forms of globoid leukodystrophy. Deficiency of the enzyme galactosylcerebrosidase was found in human cases of Krabbe's disease^{7,8} and also more recently in the twitcher mouse⁹, establishing the validity of the mutant as a model for the human disease.

Four twitcher litters (aged 40–45 days) were used, including normal and affected mice, and sciatic nerve grafts were carried out between littermates to limit as much as possible any immunological differences. Normal littermates which received twitcher transplants, originally used as controls, were expected to reject their grafts but in most cases they showed no signs of rejection. Grafts were also made from normal mice into twitchers but the life expectancy of the twitcher is so short that transplantation was carried out on 7-day-old littermates. At this age mutants were indistinguishable from their normal littermates and grafts were done at random. Successful grafts of normal sciatic nerves into twitcher sciatic nerves were achieved in two cases which survived for 35 and 37 days.

A total of 25 animals (20 normal and 5 twitchers) were grafted successfully. The results of twitcher sciatic nerve transplants into normal recipients 1–6 months after grafting are reported as well as those of the reverse experiment with 35- and 37-days

survival. To exclude the possibility of migration of Schwann cells from the proximal and distal stump into the transplant, two normal mice had the sciatic nerve severed at mid-thigh. After 48 h, at the peak of Schwann cell mitosis¹⁰, ³H-thymidine (4 µCi per g body weight) was injected intraperitoneally in each animal. After a further 24 h the two mice received a transplant from a twitcher nerve. Six months after the grafting they were perfused and blocks from proximal and distal nerve as well as from the transplant were examined using phase and electron microscopy.

One month after the operation the twitcher nerve transplant seemed to be well vascularized; many axons were myelinated and there was no sign of demyelination; Schwann cells contained no inclusions but some had abnormally watery cytoplasm with scattered organelles and the endoneurial space was greater than normal. No macrophages or inflammatory cells were seen in or around the graft. In the distal stump, axonal regeneration and remyelination followed the normal expected pattern throughout the experiment. In the transplant, endoneurial oedema was more pronounced at 2 months (Fig. 2); some fibres showed early demyelination and numerous axons were surrounded by only a Schwann cell containing myelin debris; abnormally thin myelin

Fig. 1 Electron micrographs of macrophages containing a, multi-angular bodies and b, tubules, some of which appear twisted. Similar inclusions are also found in human and canine globoid cell leukodystrophy and are considered to be characteristic of the disease. a $\times 19,000$; b $\times 36,000$.

Fig. 2 One- μ m Araldite sections of: *a*, the normal proximal region; *b*, the twitcher graft; and *c*, the distal stump 2 months after transplantation. The graft is almost double the size of the proximal nerve due to the increased cellularity, severe endoneurial oedema and abundant collagen. *a*, *b*, *c* $\times 90$.

sheaths were indicative of remyelination (Fig. 3*a*, *b*). Twisted tubules, multi-angular bodies and other inclusions were seen in Schwann cells and macrophages.

At 3, 4 and 5 months some demyelinated axons were still present, but most were surrounded by apparently normal myelin and only a few Schwann cells contained myelin debris and specific inclusions. At 6 months many fibres appeared normal although the myelin sheath thickness was not comparable with the fibres in the normal distal stump. However, at each interval some features characteristic of the twitcher were still present; these comprised specific inclusions in Schwann cells and in macrophages, an occasional demyelinated axon and some endoneurial oedema (Fig. 4*a*, *b*). Autoradiographic studies confirmed the presence of labelled Schwann cell nuclei in the distal stump but no labelled cells were found in the transplant. The normal nerve grafted into the twitcher sciatic nerve showed the opposite trend, with larger myelinated fibres in the transplant than in the proximal or distal stump. These grafted nerve fibres appeared quite normal and there was no evidence of any of the other pathological features found in the twitcher host.

These experiments show that a twitcher nerve transplanted into a normal recipient reproduces all the characteristic features of leukodystrophy and, conversely, that Schwann cells from unaffected mice can produce normal myelin when associated with twitcher axons. It can be concluded, as in analogous studies by Aguayo *et al.*^{2,3}, that donor Schwann cells are able to

Fig. 3 Electron micrographs showing *a*, the transplanted twitcher nerve and *b*, the distal stump after 2 months. In the twitcher nerve, one fibre is demyelinating and several are completely demyelinated. In a few fibres myelin appears normal. Fibres are widely separated by endoneurial oedema, excess collagen and macrophages. $\times 1,500$.

Fig. 4 Electron micrographs showing *a*, the transplanted twitcher nerve and *b*, the distal stump after 6 months. Several myelinated fibres are seen with sheaths thinner than those in the distal stump. Also visible are several inclusions in Schwann cells, a demyelinating and a thinly remyelinating fibre. The structures are more widely separated than those in the distal stump. $\times 1,500$.

reproduce an abnormality in a normal host, in association with normal axons. The twitcher axon has no apparent role in the development of the myelin sheath abnormality. Repopulation of the graft by Schwann cells from the host can be excluded on three grounds: (1) even after 6 months some specific abnormalities and abnormal myelin sheath parameters were found in the twitcher nerve grafted into a normal nerve; (2) there were neither specific inclusions nor abnormal Schwann cells and macrophages in the 37-day normal nerve transplanted into the twitcher; (3) there was no autoradiographic evidence of Schwann cell migration.

A puzzling feature was the apparent improvement towards a more normal situation in the 3–6-month grafts, which raises the question of the possible entry into the graft of enzyme from the normal host. A transitory improvement has been claimed by some authors in cases of Gaucher's disease (another enzyme deficiency condition) after transplantation of a normal spleen¹¹ and kidney¹².

The absence of rejection of the transplant without immunosuppressive treatment is unusual and does not agree with previous findings^{2–4}. It is known that a nerve transplant kept viable by anti-lymphocyte serum is quickly rejected when treatment is withdrawn³. The twitcher gene is maintained in a non-inbred strain¹ and tolerance of grafts would not be expected. The number of successful grafts in our experiment was too high to be accounted for by the random selection of immunologically matched littermates. Furthermore, a hypothetical immunological deficit in homozygous twitchers would not explain why littermates too, accept the grafts. It is possible that, although the close kinship plays a part, the non-inbred strain in which twitcher is maintained is of low immunological responsiveness¹³.

Functional nuclei of LPS-nonresponder C3H/HeJ mice after transfer into LPS-responder C3H/HeN cells by cell fusion

Takeshi Watanabe & Junichi Ohara

Department of Immunology, Saga Medical School, Nabeshima, Saga, Japan

Splenic lymphocytes of C3H/HeJ mice are defective in responding to the mitogenic activity of bacterial lipopolysaccharide (LPS)^{1–4}, which has been attributed to a mutation at a single gene locus on chromosome 4 (ref. 5). It was suggested that C3H/HeJ mice lack a cell-surface receptor necessary for LPS recognition^{6,7}. However, specific binding of ¹²⁵I-labelled lipid-A of LPS to B cells was found to be equivalent in LPS-responder and LPS-nonresponder C3H/HeJ, C57BL/10 ScCR and C57BL/10 ScN mice⁸. This suggests that the genetic defect in C3H/HeJ mice is related to triggering mechanisms rather than to LPS binding. We recently established a method for separating mouse splenic lymphocytes into karyoplasts (minicells) and cytoplasts (enucleated cells) with high purity⁹. This method makes possible the exchange of nuclei from one type of lymphocyte to another. In the present study, karyoplasts were purified from LPS-nonresponder C3H/HeJ mice and transferred to mitomycin C-treated or X ray-irradiated splenic lymphocytes taken from LPS-responder C3H/HeN mice by fusion with polyethyleneglycol. These reconstituted hybrid cells could respond to LPS, suggesting that nuclei from C3H/HeJ mice could be activated by LPS if proper signals were provided from cell-surface receptors. Moreover, responsiveness to concanavalin A (Con A) of mitomycin C-treated or X ray-irradiated lymphocytes was also recovered by the microinjection of karyoplasts from untreated lymphocytes.

Cytochalasin B is known to induce enucleation of cell monolayers through centrifugation without inhibition of protein, RNA or DNA synthesis. Furthermore, the effects of this

drug on the cell mobility, cell form or permeability are readily reversible if it is removed. Enucleation can also be carried out with mouse L cells in suspension by centrifugation in Ficoll density gradients containing cytochalasin B¹⁰. We applied the enucleation method with Ficoll density gradient centrifugation to normal murine lymphocytes (see Table 1 legend; ref. 9). Enucleation occurred almost completely after centrifugation of splenic lymphocytes in Ficoll gradients containing cytochalasin B. Karyoplasts (minicells) were further purified by 1g velocity sedimentation in gradients of bovine serum albumin. After these procedures, staining with May-Giemsa's solution revealed that contamination of cytoplasts in this fraction was <1% and no intact cells were observed. Purity of karyoplasts was also examined by measuring protein and DNA contents as well as synthesis of protein, RNA and DNA after stimulation with mitogen (LPS, Con A).

In the present study, karyoplasts were prepared from LPS-nonresponder C3H/HeJ (HeJ) mice by the above method and fused to mitomycin C-treated spleen cells of responder strain C3H/HeN (HeN). Fusion was achieved with 50% polyethylene glycol containing poly-L-arginine. The addition of poly-L-arginine greatly enhanced the fusion efficiency and ~10–20% of splenic lymphocytes were found to contain two nuclei. Viability of cells was the same before and after fusion. Neither spleen cells nor karyoplasts obtained from HeJ mice responded to LPS in the range 1–100 µg ml⁻¹ (Table 1). Mitomycin C-treated HeN spleen cells fused with HeJ karyoplasts showed a strong DNA synthetic response to LPS whereas mitomycin C-treated cells or HeJ karyoplasts did not. Peak responses to LPS were seen on day 3 with fused and intact cells (data not shown). Mitomycin C-treated HeJ cells fused with HeJ karyoplasts showed no LPS mitogenic response, but they responded to Con A. In simple mixtures of mitomycin C-treated HeN spleen cells and HeJ karyoplasts, LPS responses were not observed.

In subsequent experiments, we used irradiated (1,200 rad) spleen cells as recipients instead of mitomycin C-treated cells—similar results were obtained (Fig. 1). Reconstitution of irradiated HeN spleen cells with HeJ nuclei by polyethylene glycol-mediated fusion resulted in a significant DNA synthetic response to LPS. This did not occur when HeJ karyoplasts were

inactivated by irradiation before transfer into irradiated HeN cells, suggesting that DNA synthesis in the fused cells was due to the injected HeJ nuclei rather than the host HeN cell nuclei. Fusion of nontreated HeJ cells with HeN karyoplasts did not restore LPS responsiveness although such cells showed strong responses to Con A. These data suggest that microinjection of nuclei into cells whose own nuclei are inactivated restores DNA synthetic responses to various mitogens and that the nuclei of nonresponder strain HeJ can respond normally to LPS if stimulatory signals from cell-surface receptors are appropriate.

The C3H/HeJ defect in LPS responsiveness has been attributed to a mutation of a single gene on chromosome 4 which maps close to the Mup-1 gene¹¹. Two contradictory explanations of this abnormality have been suggested—one that the mice lack suitable cell-surface receptor which is deficient in all LPS-nonresponder strains^{6,7} and the other that the LPS triggering signal(s) is not properly transferred from cell-surface receptors to the nuclei. The latter hypothesis is based on the findings that ¹²⁵I-labelled lipid-A of LPS bound equally well to the cell surfaces of responder and nonresponder mice⁸. Another possibility is that abnormal events occur in the nucleus in response to this particular mitogen in C3H/HeJ mice. In the present study we found that LPS nonresponsiveness is attributable to cell-surface or cytoplasmic events and that nuclei are functionally intact in this nonresponder strain.

Fig. 1. Restoration of LPS responsiveness of irradiated C3H/HeN spleen cells by cell fusion. Preparations were made as described in Table 1 legend except that HeN or HeJ cells were inactivated by X-ray irradiation (1,200 rad) before fusion.

Since Carter reported¹² that the mould metabolite cytochalasin B caused nuclear extrusion of mouse L cells, this drug has been utilized to obtain large numbers of enucleated cells (cytoplasts) and minicells (karyoplasts). However, the methods have been generally limited to the cells, mainly cytoplasts, that adhere to glass or plastic coverslips after centrifugation. Wigler and Weinstein¹⁰ modified this enucleation method for use with mouse L cells in suspension. We demonstrated that separation of normal splenic lymphocytes into cytoplasts and karyoplasts without affecting cell viability, cell form and cell metabolism was possible using cytochalasin B in Ficoll gradients (Table 1). With our method, large numbers of pure karyoplasts are obtainable from normal splenic lymphocytes.

Fusion with polyethylene glycol¹³ has been extensively used for hybridization of lymphocytes and especially for monoclonal antibody-producing hybridomas or T-cell hybridomas¹⁴⁻¹⁶. We have shown here that combining polyethylene glycol with poly-L-arginine makes possible with high efficiency the fusion of

Table 1 Restoration of mitogenic response in mytomycin C-treated C3H/HeN (HeN) spleen cells after fusion with karyoplasts obtained from C3H/HeJ (HeJ) spleen cells

Responding cells	Mitogen		
	None	LPS (50 µg ml ⁻¹)	Con A (5 µg ml ⁻¹)
C3H/HeN	5,653 ± 1,122*	98,570 ± 12,682	34,193 ± 7,563
C3H/HeJ	6,025 ± 1,002	4,796 ± 310	93,029 ± 9,694

Mouse spleen cells (1×10^8 cells, viability >90%) treated with ammonium chloride to remove erythrocytes were suspended in 3 ml of Eagle's minimal essential medium (MEM) and layered on Ficoll-400 (Pharmacia) gradients (discontinuous gradients of 12.5, 15, 16, 17 and 25%) in Eagle's MEM containing $10 \mu\text{g ml}^{-1}$ of cytochalasin B (Aldrich Biochemicals) and 0.5% dimethyl sulphoxide (Sigma) in cellulose nitrate tubes. Ficoll gradients were sterilized by autoclaving. Cells were centrifuged for 70 min at 23,000 r.p.m. at 31 °C with a Beckman SW-27 swinging bucket rotor in L5-65B ultracentrifuge. After centrifugation, cells in the 17–25% Ficoll fractions were collected and washed twice with 10 vol of MEM by centrifugation at 2,000 r.p.m. for 5 min. More than 95% of the cells in this fraction were karyoplasts and these were further purified by 1g velocity sedimentation using bovine serum albumin gradients (0.5–2% in phosphate-buffered saline). After fractionation with 1g sedimentation, highly purified karyoplasts were obtained (>99% of cells were karyoplasts). Spleen cells were treated with $40 \mu\text{g ml}^{-1}$ of mitomycin C (MMC) for 40 min at 37 °C before cell fusion or culture. MMC-treated spleen cells ($1 \times 10^6 \text{ ml}^{-1}$) were mixed with karyoplasts ($1 \times 10^7 \text{ ml}^{-1}$) in Eagle's MEM. The mixtures were centrifuged for 5 min at 1,500 r.p.m. in conical tubes (Falcon no. 2095), the supernatant thoroughly removed, and three drops of 50% polyethylene glycol (Koch-light MW 6,000) in Eagle's MEM containing 10% dimethyl sulphoxide and $5 \mu\text{g ml}^{-1}$ of poly-L-arginine (Sigma) were added to the cell pellet. The tubes were gently rotated for 1 min at room temperature and the reaction stopped by adding 10 ml of pre-warmed Eagle's MEM. Cells were washed with MEM at room temperature and suspended in RPMI-1640 medium containing 10% fetal calf serum and 2 mM L-glutamine. Spleen cells (2×10^5 per well), karyoplasts (1×10^6 per well) or cells containing the hybrids (2×10^5 per well) were cultured in the presence or absence of mitogen for 72 h and pulsed with $0.5 \mu\text{Ci}$ of ³H-thymidine for the last 4 h. Bacterial LPS was *Salmonella typhosa* W0901 (Difco); Con A was from Sigma. Simple mixtures of MMC-treated HeN spleen cells and HeJ karyoplasts showed only marginal responses to LPS or Con A. MMC-treated HeN cells treated with polyethylene glycol in the same manner did not respond to the above mitogen (data not shown).

* Mean ± s.d. (c.p.m.).

normal lymphocytes with karyoplasts. This simple method for transferring intact nuclei from lymphocytes to inactivated recipient cells could be useful for studying subcellular events in lymphoid differentiation and contribute to our understanding of certain immunological disorders.

We acknowledge the suggestion of Dr T. Sekiguchi to use poly-L-arginine for cell fusion and helpful discussions with Dr Paul W. Kincade. This work was supported in part by grants from the Ministry of Education, Science and Culture, and from the Ministry of Health and Welfare, Japan.

B-cell activation by helper cells is a two-step process

Carlos Martinez-A

Basel Institute for Immunology, Grenzacherstrasse 487,
4005 Basel, Switzerland

Antonio Coutinho

Department of Immunology, Umeå University, 901 85 Umeå,
Sweden

Recent methods for assaying helper activity and cooperative induction of B cells allow for the specific interactions of large populations of lymphocytes in culture^{1,2}. These assays, which do not select for combining-site specificity of the responding B cells, were used to investigate the precise roles of direct cellular recognition and soluble mediators in the process by which specific T-helper cells stimulate resting B cells into clonal expansion and maturation to immunoglobulin secretion. We report here results demonstrating that helper cells perform two distinct functions in the process of B-cell activation: (1) on direct recognition of antigen (and restricting elements) on B-cell surfaces, helper cells induce, in a short time, target B-cell reactivity to soluble growth factors; (2) on functional recognition of antigen on 'stimulator' cells, helper cells also participate in the production of nonspecific growth factors competent to induce proliferation and maturation in those B cells that have been 'activated' by direct interaction. Either of these two steps alone is not sufficient to induce proliferation and maturation of resting B lymphocytes.

Co-culture of helper T cells specific for B-cell surface antigens with 'target' spleen cells leads to activation of large numbers of B cells that can be detected in a polyclonal plaque assay¹. Antigenic spleen cells function in this assay as 'stimulators' of helper cell activation and, in addition, the B-cell compartment of such stimulators initiates clonal expansion and maturation. As the stimulator function of spleen cells, in contrast to the B-cell responses, is radiation resistant², 'bystander' experiments can be performed to determine whether or not B-cell activation by helper cells requires direct cell-to-cell contact. Figure 1 shows the results of an experiment demonstrating that bystander, resting B cells are not activated. C3H/HeJ helper cells specific for 'minor' antigens of the C3H/Tif substrain¹ activate C3H B cells very efficiently but fail to respond to, or to activate, spleen cells of the H-2-compatible B10.Br strain. When the two types of target cells are mixed in the same culture, in which helper-cell responses are ensured by irradiated stimulator cells³, B10.Br B cells are not activated at any effector helper/target B-cell ratio. From this finding, which has also been obtained in a completely syngeneic system using hapten-specific helper cells⁴, we conclude that successful collaboration requires direct T-B-cell interactions.

The apparent requirement for direct cell interactions in cooperative B-cell activation was difficult to reconcile with the many reports that soluble helper factors are released on T-cell activation, as these would be expected to be generated *in situ* by T-cell recognition of the appropriate stimulator cells. The above results indicate that such factors are not competent to initiate the response of resting B cells.

Schreier *et al.* have recently reported that media conditioned by activated helper cells can maintain mitogen-derived blasts, but not resting B cells, in exponential growth⁵. To assess the generation of such B-cell growth factors in our cultures, we repeated the above experiments using lipopolysaccharide (LPS)-activated B-cell blasts as bystander cells. As shown in Fig. 2, activation of helper cells by the irradiated stimulator cells

Fig. 1 The helper activity of C3H/HeJ anti-C3H/Tif helper cells, prepared as described elsewhere¹ by *in vivo* priming and *in vitro* enrichment for 4 weeks, was tested by mixing the indicated numbers with 3×10^4 target C3H/Tif (▲) spleen cells in 0.2-ml cultures in RPMI-1640 medium supplemented with 2-mercaptoethanol and 10% fetal calf serum¹. In parallel cultures helper cells were titrated into mixtures of 3×10^4 bystander B10.Br small spleen cells purified by density gradient centrifugation, with the same numbers of irradiated (3,300 rad) C3H/Tif spleen cells (◆). The IgM-secreting plaque-forming cell (PFC) responses were determined in the protein A plaque assay²⁴ 5 days later. Control responses of the same spleen cells to the B-cell mitogen LPS are also shown. Helper cells incubated with resting B10.Br spleen cells alone induce no response (■)¹.

does result in the generation of factors that maintain exponential growth and maturation in unrelated B-cell blasts.

Taken together, these results suggest that helper T cells, in addition to their role in the production of soluble nonspecific growth factors, also induce in resting B lymphocytes a state of responsiveness to those growth factors. This first step in the induction process could presumably explain the requirement for direct interactions. However, this model could only be confirmed by showing that the initial contact of resting B cells with specific helper cells could induce the 'transition' in the reactivity of the responding B cells to growth factors. In fact, the experiments with mitogen-derived B-cell blasts give no information on the initiation of helper cell-dependent induction.

To investigate these possibilities, trinitrophenyl (TNP)-derivatized BALB/c spleen cells were incubated for 48 h with specific BALB/c anti-TNP-BALB helper cells². These cultures were then depleted of T cells and the B-cell blasts originating from this initial T-B-cell interaction were purified and added as bystander cells to cultures where B10.Br anti-NP-B10.Br helper cells were stimulated by the appropriate (NP-self) irradiated spleen cells. As shown in Fig. 3, B-cell blasts activated by the cooperative interaction maintain exponential growth and maturation if unrelated T-helper cell activity takes place in the same culture. Bystander blast responses, however, strictly require concomitant, though unrelated, activation of helper cells, as there is no growth in cultures where all these cell populations were also present but the irradiated B10.Br stimulator cells were not hapten-derivatized. This control excludes 'background' activation of blasts, as well as direct interaction of NP-specific B10.Br helper cells with the BALB/c B-cell blasts. Our results demonstrate that initial T-B-cell interactions result in the acquisition of responsiveness to soluble nonspecific growth factors by the activated B cells. In addition, they show that B cells 'poised' to respond require additional soluble factors to initiate and/or maintain exponential growth.

Cooperative B-cell responses can therefore be separated into two distinct phases of which only the initiation requires direct contact with specific helper cells, whereas expansion is mediated

by soluble B-cell growth factors generated independently by helper cell interaction with competent antigen-presenting cells. It remains to be investigated whether the same helper cell is competent at the two different response levels, or whether functionally distinct T-cell subsets are involved in the initiation and expansion of B-cell responses. The cellular origin of B-cell growth factors, and their molecular characteristics are also unknown. On the other hand, previous experiments in this system have confirmed, with one exception³, the strict major histocompatibility complex restriction of the direct helper cell-B cell interactions⁴, regardless of the nature of the B-cell antigens recognized. It seems, therefore, that I-A- or I-E (C)-encoded⁶ structures on B-cell surfaces are the receptors for the helper cell signals resulting in the transition to responsiveness to B-cell growth factor. As the present experiments were performed in the absence of antigen recognition by the responding B cells whereas activation required specific antigen recognition by helper cells on B-cell surfaces, we suggest that the only role of antigen recognition (immunoglobulin-receptor binding) by B cells is that of making the antigen available on specific B-cell surfaces for T-helper cell recognition, thereby ensuring direct interaction and Ia-mediated induction⁷. These results agree with those demonstrating the necessity for specific helper cells and the failure to substitute for them with soluble factors in the response to protein antigens^{8,9}.

Classical observations, such as the requirements for 'linked recognition' of hapten-carrier conjugates and for the presence of more than one antigenic determinant in immunogenic molecules^{10,11} as well as the unidirectionality of the allogeneic effect *in vivo*^{12,13} can also be explained by this model. More recent results demonstrating the I restriction of T-B-cell interactions^{14,15} and the tendency to 'monogamy' of specific helper cells¹⁶ also fit in with the present schematic framework.

In contrast, the classical bystander experiments of Hartmann¹⁷, Schimpl and Wecker¹⁸ and Dutton *et al.*¹⁹ are in apparent contradiction with the present model. As pointed out by others^{8,9}, however, the *in vitro* responses to sheep erythrocytes are the exception rather than the rule in their lack of requirement for specific helper cells. *In vivo* experiments show no bystander effects and the responses require direct recognition of antigen by helper cells on B-cell surfaces^{15,20}. The *in vitro*

Fig. 2 B10.Br in B-cell blasts, purified by density gradient centrifugation²⁵ after 48 h of LPS stimulation were recultured (3×10^4 per culture) either alone (filled symbols) or with 3×10^4 irradiated (3,300 rad) C3H/Tif spleen cells (open symbols). Both types of cultures were stimulated with either LPS (Δ , $\blacktriangle$) 10^4 C3H/HeJ anti-C3H/Tif helper cells ($\square$, $\blacksquare$), prepared as described in Fig. 1 legend, or left untreated ($\circ$, $\bullet$). The IgM PFC responses were determined at the indicated times.

Fig. 3 Specific BALB/c anti-TNP BALB/c and B10.Br anti-NP B10.Br helper cells used in these experiments were obtained as summarized in Fig. 1 legend, and previously described in detail, by immunization with BALB/c spleen cells derivatized with TNP or B10.Br spleen cells coupled with NP², respectively. In a first culture, TNP-derivatized BALB/c small spleen cells, purified by density gradient centrifugation, were incubated with BALB/c anti-TNP BALB/c-specific helper cells at a 3:1 ratio. After 48 h, B-cell blasts were isolated from this culture by density gradient centrifugation, followed by treatment with anti-Thy-1 antibodies and complement, and used in the test cultures shown. These contained B10.Br anti-B10.Br-NP helper cells that were cultured at the indicated concentrations with 3×10^4 non-irradiated, non-derivatized ($\square$) or NP-derivatized ($\blacktriangle$) B10.Br spleen cells. Parallel cultures of helper cells were stimulated with the same number of irradiated (3,300 rad) B10.Br spleen cells, either normal ($\circ$) or NP-derivatized ($\bullet$) and also received 3×10^4 purified BALB/c B-cell blasts isolated from the first culture. The IgM PFC responses were measured on day 4 of culture. Open symbols represent numbers of IgM PFC observed in each type of spleen cell culture, in the absence of helper cells. No PFC responses were observed in mixed cultures of helper cells with irradiated B10.Br spleen cells, either normal or NP-derivatized (not shown).

bystander effects can be made compatible with the present model by attributing the exceptional behaviour of sheep erythrocytes to their ability to induce, in resting B cells, the transition in reactivity to growth factors²¹⁻²³.

Clones of helper T cells mediate antigen-specific, H-2-restricted DTH

It is now well established that in the mouse, helper T cells and killer T cells are two distinct thymus-derived lymphocyte subpopulations, differing from each other in Lyt phenotype and H-2 restriction, among other parameters. Helper T cells are Lyt-1⁺ and their action in immune responses involves restriction at the H-2I region of the major histocompatibility complex (MHC)^{1,2}. Killer cells, on the other hand, are Lyt-23⁺ and their activity is restricted by H-2K/D (refs 1, 3). In most instances, T cells mediating delayed-type hypersensitivity (DTH) responses share the Lyt phenotype and H-2 restriction of the helper T cell⁴⁻⁷. This raises the question of whether or not helper activity and DTH can be mediated by the same activated T cell. Arguments for both views have been reported⁸⁻¹². We analysed this question using clones of specific helper T cells, which were obtained by long-term culture *in vitro* of *in vivo* primed T cells, followed by single-cell cloning¹³⁻¹⁵. Here we show that these clones of helper T cells mediate antigen-specific and fully H-2-restricted DTH. The restricting element lies to the left of the I-B region in genetic maps of the mouse MHC.

Long-term cultured, cloned and subcloned sheep or horse red blood cell-specific helper T cells (T'_{SRC}, T'_{HRC} respectively), which have been maintained for 5-24 months in culture and previously shown to function as helper T cells *in vitro*¹³⁻¹⁵ and *in vivo*¹⁵, were examined for DTH activity. This DTH responsiveness was assayed by means of the immune lymphocyte transfer assay¹⁶. As few as 1,000 cloned helper T cells, injected together with SRC into syngeneic recipients, caused a significant DTH response which increased in severity as the dose of T cells increased (Fig. 1). In comparison with *in vivo* activated lymph node cells, the cloned helper T cells were far more effective on a per cell basis. At least 10³ times more *in vivo* activated cells were required to induce a response of similar magnitude (Fig. 1, right). As controls, the other footpad of the mice was injected with cloned helper T cells without antigen or with an irrelevant antigen—in neither case was a DTH response induced. DTH responses were mediated equally well by other clones of T'_{SRC} and T'_{HRC} and by four different clones of egg albumin-specific helper T cells when injected together with the relevant antigen.

The H-2 restriction of cellular interactions involved in DTH responses¹⁷ was examined using a clone of T'_{SRC} and a subclone of T'_{HRC}. Absolute H-2 restriction was observed in both instances. Results obtained with T'_{SRC} (clone 26-14) are shown in Fig. 2. The C57BL/6J-derived cloned helper T cells mediated DTH responses only in the C57BL/6J and B10.A(5R) recipients. B10.HTT mice (incompatible with C57BL/6J mice for the whole H-2 complex) and B10.A(4R) mice (incompatible at H-2K and I-A) did not show any DTH reactivity on injection of the cloned helper T cells plus antigen. It should be stressed that this result was found after transfer of 3.3 × 10⁴ viable T cells, which is about 30 times the number of cells required to induce a significant response in a syngeneic combination. This result shows that the T cell-macrophage interactions which underlie

these DTH responses¹⁷ are restricted by either H-2K or I-A. Appropriate congenic strains were not available at the time of these experiments for distinguishing between K- or I-A-region restriction. However, the action of helper T cells in immune responses *in vivo* has been demonstrated to involve restriction only at I-A².

The antigen-specific and H-2-restricted induction of DTH response with cloned helper T cells in normal mice does not exclude the participation of host T cells at the effector level. We have therefore tested the DTH response induced by cloned helper T cells in congenic *nu/nu* mice (Fig. 2). The DTH response in these T cell-deficient animals showed the same kinetics as and was of similar magnitude to that observed in thymus-bearing, I-A-compatible mice. This result indicates that host T cells are not essential for the response and that the cloned helper T cells are the DTH effector cells.

Many investigations have attempted to establish the relationship between helper T cells and DTH effector cells⁸⁻¹². Although some studies pointed to an inverse relationship between the *in vivo* occurrence of activated helper T cells and DTH effector cells⁸⁻¹⁰, others have found that helper activity and DTH can coincide^{11,12}. These experiments were carried out with uncloned T-cell populations and failed to prove that both responses can be mediated by the same cell. However, our experiments show unequivocally that helper T cells can mediate DTH responses which were observed not only in the local immune lymphocyte transfer assay, but also after intravenous injection of these cells. Mice infused with 1-3 × 10⁶ cloned helper T cells responded to antigen challenge to the hind footpad with a smaller but significant DTH response. This requirement for much higher numbers of cells may be due to changes in recirculation and

Fig. 1 DTH sensitivity by different numbers of long-term cultured C57BL/6J-derived, SRC-specific helper T cells (clone S26-14) (left), and by different numbers of lymph node cells which were activated *in vivo* by subcutaneous immunization of C57BL/6J mice with 2 × 10⁷ SRC (right). The cells to be tested were injected together with 5 × 10⁷ SRC in a volume of 50 µl into the instep of the right hind leg of C57BL/6J female mice (Institut für Biologisch-Medizinische Forschung AG). Recipient mice injected with cloned SRC-specific helper T cells plus SRC in the right hind leg received the same number of HRC-specific helper T cells (subclone 18-33-3) together with 5 × 10⁷ SRC in the left hind leg. Recipient mice which received *in vivo* activated lymph node cells plus SRC in the right hind leg received the same number of non-activated lymph node cells and 5 × 10⁷ SRC in the left hind leg. At 24 h after injection the thickness of the hind feet was measured. DTH responses are expressed as the specific % increase in foot thickness, and were calculated as (thickness right foot - thickness left foot)/thickness left foot × 100%. Horizontal bars represent 1 s.e.m. (n = 7). ND, not determined. *, The establishment and maintenance of the long-term cultured specific helper T cells has been described previously¹³⁻¹⁵. †, The activated lymph node cells were obtained by collecting the inguinal and axillary lymph nodes of C57BL/6J mice 4 days after subcutaneous immunization with 2 × 10⁷ SRC, equally distributed over the inguinal and axillary areas. The non-activated lymph node cells were obtained from naive C57BL/6J mice.

* On leave of absence from the NIH, NIA, Bethesda, Maryland 20205, USA.

Fig. 2 DTH reactivity mediated by cloned SRC-specific helper T cells was tested for H-2 restriction. Recipient mice (all from the Institut für Biologisch-Medizinische Forschung AG) were injected with 3.3×10^4 SRC-specific helper T cells (clone S26-14) and 5×10^7 SRC in a volume of $50 \mu\text{l}$ in the instep of the right hind foot, and with 3.3×10^4 HRC-specific helper T cells (subclone 18-33-3) and 5×10^7 SRC in the instep of the left hind foot. At 24 h after transfer the thickness of the hind feet was measured. DTH responses are expressed as the specific percentage increase in foot thickness and calculated as described in Fig. 1 legend. Horizontal bars represent 1 s.e.m. ($n = 7$).

homing properties brought about by long-term *in vitro* propagation. Similar observations were made in clonally reconstituted *nu/nu* mice where $1-5 \times 10^6$ of the same cloned helper T cells were required to induce specific antibody responses comparable with or higher than those observed in thymus-bearing mice¹⁵.

Obviously, our results do not argue against the possibility that T cells other than helper T cells may also mediate DTH reactivity. Several studies have shown that DTH to allogeneic cells can be transferred by Ly-2⁺ cells⁷ and that contact sensitivity to dinitrofluorobenzene⁶ and DTH to non-H-2 alloantigens¹⁸ and viral antigens¹⁹ can be H-2K/D restricted. Indeed, it has been reported that T cells mediating DTH and cytotoxic T cells could not be separated by size, density or antigen-binding properties²⁰.

The clones of helper T cells used for these studies have been shown to release several biologically active mediators, the induction of which is strictly antigen specific and H-2 restricted^{13,14,21-23}. So far, factors affecting B-cell^{21,22} and T-cell¹⁴ growth and *in vitro* colony formation by granulocytic, macrophage and erythroid precursor cells²³ have been discerned. Soluble factors have been indicated in the induction of the DTH lesion²⁴. Histologically, the DTH response mediated by cloned helper T cells in *nu/nu* and normal mice was indistinguishable from other Jones-Mote-type DTH responses. The nature of the cellular infiltration strongly indicates the release of chemotactic factors. Clones of helper T cells may help to characterize these activities. In addition, the DTH response is the most rapid assay to date for screening cloned and uncloned helper T cells for specificity and H-2 restricted activity. The assay is as sensitive and reproducible as the *in vitro* assay for specific helper activity. Moreover, the cellular nature of the I-A-bearing, antigen-presenting cells may be identified by their simultaneous injection with helper T cells into I-A-incompatible hosts.

Altered expression of the calcitonin gene associated with RNA polymorphism

The selective control of gene expression results in diversified morphology and physiological function. Understanding the expression of differentiated function in molecular terms requires detailed characterization of the regulation of mRNA synthesis and catabolism. Although considerable emphasis has been placed on transcriptional control, the discovery of HnRNA and 'split genes' gives rise to the possibility of post-transcriptional regulation at the level of processing of nuclear precursors^{1,2}. A rat calcitonin-producing medullary thyroid carcinoma (MTC) line was used as a model for definition of certain aspects in regulation of gene expression. Serial transplantation of several rat MTC lines containing and secreting large amounts of calcitonin generated tumours in which calcitonin biosynthesis was decreased more than 10-fold. We report here that the conversion from a 'high' to a 'low' calcitonin producing state is associated with specific modifications of the calcitonin mRNA synthetic pathway and a consequence of these changes seems to be the production of a new cytoplasmic mRNA.

Variation in calcitonin biosynthesis typifies a frequent event in many hormone-producing tumours characterized by a spontaneous reduction in synthesis of a particular hormone, often in association with the appearance of new and frequently predictable hormones³. Thyroid 'C'-cell hyperplasia and ultimate development of MTCs occurs in 10–40% of older rats⁴. Production of calcitonin by these tumours may decrease spontaneously during a single transplantation or following reintroduction of primary culture cells, or gradually during serial transplantation, from the usual 1.5–4.5% of total protein to <0.3% of total protein⁵. The direction of change is characteristically from high to low calcitonin production. Immunohistochemical staining with specific calcitonin antisera reveals that ~95% of the cells in high-producer tumours and <5% of cells in low-producer tumours are calcitonin positive. The conversion to low calcitonin production is frequently accompanied by increased production of somatostatin⁶. These tumours also produce other polypeptide hormones⁷.

Characterization of rat calcitonin mRNA has allowed detailed analysis of calcitonin biosynthesis. mRNA from MTCs programmes the cell-free synthesis of a calcitonin precursor peptide of molecular weight (MW) 17,500 (ref. 8) (alternatively estimated as 15,000 (ref. 9)) and a less prevalent product of MW 18,800 (ref. 8). DNA sequence analysis of a chimaeric plasmid containing DNA complementary to calcitonin mRNA establishes that the 32-amino acid calcitonin sequence is encoded in the 3'-proximal portion of the mRNA¹⁰. Using this clone as probe, normal rat thyroid and high-producer rat MTCs

Fig. 1 Analysis of RNA species hybridizing to calcitonin cDNA. Poly(A)-rich RNA was prepared as described elsewhere^{8,11} from high- and low-producer tumours. Aliquots were denatured by reaction with glyoxal¹² and electrophoresed on 1.5% agarose slab gels using 36 mM Tris-HCl (pH 7.6), 30 mM NaH₂PO₄·H₂O, 1 mM EDTA¹³. The gel was stained using acridine orange, photographed and gently shaken for 20 min with 50 mM NaOH, then neutralized with two washes of 0.2 M sodium acetate (pH 4.3). The RNA was then transferred to diazotised paper, washed in prehybridization solution, and hybridized for 14 h at 42 °C against 5×10^5 c.p.m. ml⁻¹ of ³²P-labelled calcitonin cDNA, produced by nick-translation of calcitonin-containing plasmid to a specific activity of 1.5×10^8 c.p.m. μ g⁻¹ (refs 13, 14) using dCTP as the labelled nucleotide. The paper was washed and autoradiographed as previously described. The migration of 18S and 28S ribosomal RNAs and of prolactin mRNA was used to calculate size; the portion of the gel which was blotted contained 18S RNA, as shown. The 1,050-nucleotide species is referred to as calcitonin mRNA. *a*, Poly(A)-rich RNA from a high-producer tumour (10 μ g); *b*, poly(A)-rich RNA from a low-producer tumour (10 μ g).

Fig. 2 Analysis of total cellular RNA species hybridizing to calcitonin cDNA. Poly(A)-rich RNA was prepared and processed as described in Fig. 1 legend. The autoradiograph was exposed for 4 days to visualize clearly the larger reactive RNA species. Lane 1, cytoplasmic poly(A)-rich RNA (5 μ g) from a high-producer tumour; lane 2, total poly(A)-rich RNA (10 μ g) from a high-producer tumour; lane 3, total poly(A)-rich RNA (10 μ g) from a low-producer tumour; and lane 4, total poly(A)-rich RNA (10 μ g) from a low-producer tumour of independent origin.

were shown to contain one major poly(A)-rich cytoplasmic RNA species $1,050 \pm 50$ nucleotides in length¹⁰, referred to as calcitonin mRNA.

To identify mechanisms by which variation in calcitonin gene expression occurs, total poly(A)-rich RNA for high- and low-producer tumours was examined. Analyses were carried out by hybridizing labelled, cloned calcitonin cDNA to RNA transferred to diazotised paper after denaturation and size-fractionation through agarose gels (see Fig. 1 legend). In the conditions used, this method provided an accurate and reproducible quantification of RNA species which varied from 1,000 to 5,500 nucleotides in length over a 200-fold range of

Fig. 3 Scan analysis of autoradiographs of calcitonin cDNA-reactive species. Autoradiographs of calcitonin cDNA-reactive RNA were quantified by scanning with a Helena Quickscan (1-mm window). The sizes of various RNA species are indicated, based on migration of 18S and 28S rRNA. —, High- and - - -, low-producer tumour RNA.

RNA concentration. Remarkable differences in the abundance and size of reactive poly(A)-rich RNA from low-producer tumours were observed. As shown in Fig. 1b, low-producer tumours contain a 1,050-nucleotide transcript which co-migrates with calcitonin mRNA of both high-producer tumours and normal thyroid gland, and a second abundant species which migrates at 150–250 nucleotides longer than calcitonin mRNA (Fig. 1a). Note that this second species seems to lack a similar correspondent in the high-producer lines which suggests that conversion from high to low production is associated with an altered expression of the calcitonin gene or a closely related gene.

To examine this relationship more closely, it is necessary to identify the steps involved in the synthesis of mature calcitonin mRNA. Total poly(A)-rich RNA from high- and low-producer tumours was examined for putative precursor transcripts. In addition to the prominent 1,050-nucleotide cytoplasmic species, RNA from the high-producer tumour contains several calcitonin cDNA-reactive RNA species (Fig. 2, lanes 1 and 2). These include transcripts of 6,400, 5,200, 4,200, 3,800, 3,100, 2,200 and 1,800 nucleotides in length.

Analysis of RNA from two independent low-producer tumours revealed surprising alterations in abundance of most of the nuclear transcripts. There were large increases in the 6,400-, 5,200-, 4,200- and 3,800-nucleotide species whereas the 1,800-nucleotide transcript was significantly decreased (Fig. 2, lanes 3 and 4). The abundant RNA species are overexposed on the autoradiograph (Fig. 2) to visualize the less-abundant putative nuclear RNA species.

Scans of the autoradiographs (Fig. 3) allowed quantification of reactive RNA species. The amount of the 3,800-, 5,200- and 6,400-nucleotide RNA species in low-producer tumours was increased 10- to 30-fold above that in high-producer tumours. In the low-producer tumour, the 3,800-nucleotide RNA species alone bound up to 25–30% of the total probe hybridized. There was no alteration between high- and low-producer tumours in the amount of reactive 3,100- or 2,200-nucleotide RNA species.

Conversion to a low calcitonin producer state was associated with a series of reproducible alterations in calcitonin gene expression. Cells which contained little or no detectable calcitonin transcribe large amounts of calcitonin-reactive nuclear RNA species and generate new cytoplasmic RNA species, 150–250 nucleotides larger than the 'mature' calcitonin mRNA.

The molecular alterations which occur during conversion from high to low calcitonin production could result from one of several possible mechanisms: (1) an increased transcriptional activity of a related gene (or genes), with concomitant reduced expression of the calcitonin gene, corresponding to the reduction in calcitonin synthesis; (2) an alteration in the primary structure of a single calcitonin gene, with resultant alteration in processing of the primary transcript; or (3) the observed RNA heterogeneity in low-producer tumours arises from differential or 'abnormal' processing of one primary RNA transcript. In the latter two cases, the increased abundance of the putative nuclear precursor RNAs could correspond to an altered processing pathway; any of the proposed models could result in the observed RNA polymorphism. To investigate these possibilities, a chimaeric plasmid containing DNA complementary to the additional RNA sequence unique to the new 1,250 RNA present in low-producer tumours has been constructed. This will allow initiation of structural and functional analysis of the new cytoplasmic RNA species, the putative nuclear RNA transcripts, and of the calcitonin gene.

Dual expression of λ genes in the MOPC-315 plasmacytoma

Alfred L. M. Bothwell, Michael Paskind, Richard C. Schwartz, Gail E. Sonenshein*, Malcolm L. Gefter & David Baltimore

Center for Cancer Research and Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

The expression of two distinct κ light chain immunoglobulins in the MPC-11 mouse myeloma is well established^{1–4}, the two protein products being apparently from RNA transcripts derived from separate, rearranged κ alleles in the MPC-11 genome^{5–7}. Recently, the characterization of κ -related RNAs and protein products in several λ -producing myelomas has indicated that multiple expression of light chain RNAs is a common event in myelomas and other cells of the B-lymphocyte lineage⁸. These studies suggest that, although many light chain alleles may function to make RNA and protein in a given B-lymphocytic cell, only one complete, functional light chain is generally translated from the RNAs present in a single cell. The myeloma, MOPC-315, synthesizes and secretes an antibody

* Present address: Boston University Medical School, Department of Biochemistry, Boston, Massachusetts 02118, USA.

which has an α heavy chain and a λ_{II} light chain⁸. The DNA of MOPC-315 either has no κ genes or has only a fragment of one, but it certainly has no κ genes in the embryonic configuration⁵. Rearrangement of its λ genes has been observed but the exact nature of the rearrangement is not known⁹. Because initial observations suggested that an immunoglobulin-related protein other than α and λ_{II} was present in MOPC-315 cells¹⁰, we undertook to derive molecular cDNA clones from the mRNA in MOPC-315 tumour cells. Analysis of the clones has now identified two λ chain mRNA species: a normal λ_{II} chain mRNA and another which directs the synthesis of a deleted form of a λ_I protein. The nucleotide sequence of the deleted λ_I mRNA shows that it resulted from a joining of the sequence encoding amino acid 31 of the variable region directly to the constant region coding sequence.

To characterize the λ RNA and protein products in MOPC-315 we first derived cDNA clones from total poly(A)-containing RNA of the tumour. In parallel, *in vitro* translation studies on partially purified mRNAs and RNA size analysis with cloned λ probes were performed¹⁰. Clones were derived using the dG-dC homopolymer tailing method to insert DNA in the *Pst*I site of pBR322. After transformation of *Escherichia coli* χ 1776, recombinant plasmid-containing cells were selected that hybridized to a full length λ_I cDNA clone previously derived from myeloma MOPC-104E (A.L.M.B., unpublished). Preliminary restriction enzyme digest patterns indicated the presence of two types of λ cDNA clones. Two of the longest clones representative of the two classes of inserts were chosen for detailed examination. Because one was shown to have λ_{II} sequence and the other λ_I sequence, they were named $p\lambda_{II}$ -1 and $p\lambda_I$ -13.

The relationship of the clones to cellular mRNAs was studied by using the cDNA clones to select mRNA by hybridization and

Fig. 2 Restriction maps of the λ_I and λ_{II} cDNA clones. The maps indicate the deletion of the 3'-proximal two-thirds of the variable region and J region from $p\lambda_I$ -13 when compared with the normal λ mRNA. The $pAB\lambda_I$ -1 clone (from MOPC-104E, a λ_I producer) contains a portion of the leader sequence whereas the $p\lambda_I$ -13 clone begins at amino acid 8 in the mature protein. The embryonic λ_{II} variable sequence does not contain a *Bam*HI site¹³. A different amino acid occurs at amino acid position 38 (isoleucine) in the MOPC-315 λ_{II} sequence from that predicted from the germ-line λ_{II} variable gene DNA sequence (valine)¹³. The codon ATC for residue 38 (isoleucine) would generate a *Bam*HI site which is found in $p\lambda_{II}$ -1. bp, base pairs.

Fig. 1 *In vitro* translation of clone selected mRNA. Either an *Eco*RI-*Xho*I 1,100-base pair DNA fragment derived from $p\lambda_I$ -13 plasmid (10 μ g) or a *Pvu*II-*Ava*I 1,800-base pair DNA fragment derived from 10 μ g of $p\lambda_{II}$ -1 containing the λ_{II} constant region was denatured and bound to a nitrocellulose filter and hybridization and elution procedures performed¹⁸. Membrane-bound poly(A)-containing polysomal RNA (5 μ g) derived from MOPC-315 (tumours maintained by Dr H. Eisen) was hybridized in 65% formamide, 400 mM NaCl, 10 mM PIPES, pH 7.4, at 45 °C for 2 h. The filters were washed 10 times with 150 mM NaCl, 20 mM Tris-HCl pH 7.8, 1 mM EDTA, 0.5% SDS at 65 °C, then three times in 20 mM Tris-HCl pH 7.8, 1 mM EDTA. RNA was removed by boiling for 1 min with 300 μ l of H₂O, ethanol precipitated and translated in a rabbit reticulocyte lysate. Lanes contain total polysomal RNA translation products (lanes 1-3), $p\lambda_I$ -13-selected mRNA translation products (lanes 4-6) or $p\lambda_{II}$ -1-selected mRNA translation products (lanes 7-9). Products in lanes 2, 5 and 8 were precipitated with anti- λ_I serum and those in lanes 3, 6 and 9 with anti- λ_{II} serum. The sources of the antisera and immunoprecipitation procedures are described elsewhere¹⁰.

then translating the mRNAs *in vitro* (Fig. 1). Two λ -related protein products could be detected by *in vitro* translation of mRNA. When the total translation products (lane 1) were submitted to specific immunoprecipitation, an 18,000 molecular weight (18K) protein was precipitated with anti- λ_I serum (lane 2) and the complete λ_{II} light chain was precipitated with anti- λ_{II} serum (lane 3). When the mRNA selected by $p\lambda_I$ -13 was translated, an 18K protein was enriched (lane 4) which was precipitable with anti- λ_I serum (lane 5) but not with anti- λ_{II} serum (lane 6). By contrast, when $p\lambda_{II}$ -1 was used to select mRNA, the selected mRNA translated into λ_{II} protein (lane 7) which was not precipitable with anti- λ_I serum (lane 8) but was precipitable with anti- λ_{II} serum (lane 9). We have independently shown that the $p\lambda_{II}$ -1 clone hybridizes to a mature size light chain mRNA (1,100 base pairs) whereas the $p\lambda_I$ -13 clone hybridizes to a mRNA of about 900 base pairs¹⁰. Thus, it is evident that MOPC-315 cells have two types of λ -related mRNA which gave rise to two classes of clone: $p\lambda_{II}$ -1 derived from a full-length mRNA encoding the λ_{II} protein of MOPC-315 antibody and $p\lambda_I$ -13 derived from a truncated λ_I mRNA that translates to form a truncated λ_I -related protein.

The $p\lambda_I$ -13 clone was further analysed by comparing its restriction enzyme digest pattern with that of a clone derived from the full-length λ_I mRNA of myeloma MOPC-104E prepared in this laboratory (A.L.M.B., unpublished) (Fig. 2). The authentic λ_I clone had six identifiable sites, two of which (*Xho*I and *Kpn*I) in the constant region would not have been predicted from the reported 138-base pair sequence¹¹. Sequence data, reported below, have confirmed the existence of these sites in this and in other λ_I cDNA clones; presumably, there were sequencing errors in the previous report. The $p\lambda_I$ -13 clone from MOPC-315 had all the sites found in the authentic λ_I constant region sequence. These distinguish the cloned insert from the λ_{II} genes, the sites of which are quite different from those in the λ_I gene (Fig. 2).

To analyse the structure of $p\lambda_I$ -13 further, we determined the nucleotide sequence of its insert (Fig. 3). The entire constant region sequence was evident but the variable region sequence contained codons that, by comparison with the reported protein

The origin of the λ_1 mRNA in MOPC-315 is uncertain. A DNA rearrangement has probably occurred because the λ_1 variable and constant regions are found on a single mRNA. Analysis of λ genes in MOPC-315 DNA indicates that the only detectable λ_1 rearrangement involving both the variable and constant regions is the normal V_1 to C_1 rearrangement. The 7.4-kilobase fragment co-migrates with the fragment observed in the λ_1 producer, MOPC-104E (A.L.M.B. and D.B., unpublished results). Therefore, the rearrangement, or somatic mutation, must have altered the normal donor site at the 3' end of the J segment. Whether the entire λ_1 variable region is present in the DNA is uncertain and will necessitate fine structure analysis: the deletion of a variable region sequence in the mRNA could result from either an aberrant DNA rearrangement that removed the coding sequence for amino acids 32-109 or from an aberrant RNA splicing event. Precedent for aberrant splicing as a cause of variable region deletion in a mRNA comes from the case of MPC-11 (refs. 6, 7), in which on one chromosome a κ variable

The possibility of an aberrant splice as the cause of the truncated λ_1 mRNA in MOPC-315 is supported by an examination of the nucleotide sequence of the λ_1 variable region. The sequence TAGTAATA that occurs immediately 3' to the deletion site in the complete λ_1 variable region¹¹ has the form close to the canonical donor splice sequence^{14,15}. It is also clear from a comparison of the cleavage points demanded by the sequence of the cDNA clone (indicated by arrows)

Fig. 3 Nucleotide sequence of p λ I-13. The sequence of the insert was determined by both the Sanger dideoxynucleotide extension procedures according to Maat and Smith¹⁹ and the Maxam-Gilbert methods²⁰. The sequence of both strands was determined by kinase treatment at the following sites: *Pst*I, *Xho*I, *Pvu*II and *Mbo*II (at position 207). The two residues below the sequence (G, T) are the only differences between the λ I and λ II variable regions in this clone. The numbers above the translation sequence are the amino acid positions in the mature protein and the numbers below the DNA sequence indicate the number of base pairs from the first nucleotide in the inserted λ I sequence as it is drawn here.

Recombination suppression of mouse *t*-haplotypes due to chromatin mismatching

Lee M. Silver* & Karen Artzt

Sloan-Kettering Institute for Cancer Research, New York, New York 10021, USA

We show here that recombination occurs at the normal rate in compound female mice containing two different complementing lethal haplotypes (t^{h17}/t^{w12}) where there is a long stretch of homologous *t*-mutant chromatin. Thus the recombination suppression of a complete *t*-haplotype cannot be due to an intrinsic factor(s) which suppresses along the length of its own chromosome but is due to 'mismatching' of wild-type and mutant chromatin. Naturally occurring *t*-haplotypes of mouse chromosome 17 have several interesting genetic properties. First, they are always transmitted from males in much higher proportions than mendelian expectation; presumably this accounts for the maintenance of lethal and semilethal *t*-haplotypes at polymorphic levels in populations of wild mice. *t*-Haplotypes also show recombination suppression. The conventional map distance between genetic markers *T* and *tf* is 7–12 cM, whereas in (*t*/+) heterozygotes for naturally occurring *t*-haplotypes, recombination is suppressed and *T* and *tf* seem to be separated by only 0.1–0.5 cM (ref. 1). The region of recombination suppression extends to and includes the major histocompatibility complex (H-2)². Thus *t* and H-2 effectively travel as a single unit—a 'super gene'³. Although recombination suppression is known to be accompanied by failure of chiasmata formation⁴, the mechanism underlying the suppression has remained an enigma. Lyon suggested a disorder of *t*-heterochromatin⁵ and more recently a change in 'intercalary' middle repetitive DNA⁶. She proposed that either *t*-chromatin is intrinsically incapable of participating in crossing-over, or chiasma formation is prevented because of mismatching and mispairing of normal and abnormal chromatin. We have measured recombination between two chromosomes which carried extensive overlapping segments of *t*-chromatin. We report here that in this configuration, recombination occurs at a normal rate, and thus we conclude that cross-over suppression is due to mismatching.

Rare recombination events do occur in *t*/+ heterozygotes and produce reciprocal cross-over products that are profoundly different. Whereas intact *t*-haplotypes contain a factor responsible for interaction with *T* to produce taillessness as well as a recessive lethal factor, those recombinants that retain the centromeric end of the parent *t*-haplotype continue to interact with *T* to produce taillessness, but are no longer lethal when homozygous, and those that acquire the distal end of the original *t*-chromosome retain the lethal factor but no longer show any interaction with *T*. Both cross-over products show limited recombination suppression in heterozygotes: *t*-viable haplotypes suppress it about half-way through the *T*-*tf* interval but not beyond⁷; *t*-lethal haplotypes seem to continue to be inextricably linked to H-2 although they permit free recombination between *T* and *tf*⁸.

Lyon investigated the problem of cross-over suppression by measuring recombination between recombinant chromosomes that contained, in one case, the proximal end and in the other the distal lethal factor, and which were thought to have a short overlapping region of *t*-chromatin. Using t^{h2} and t^{h17} (see Fig. 1a) she found very low recombination (1.5% compared with 18.1% expected for $t^{h17}/+$), and concluded that each *t*-haplotype suppressed recombination over its own length. She also

tested several haplotypes that are thought to be non-overlapping, and found that crossing-over was normal where the wild-type chromatins coincided (Fig. 1b, for example). These experiments did not rule out the possibility that cross-over suppression is due to mismatching of *t* and wild-type chromatin.

The characteristics of the two chromosomes we used (see Fig. 2) were as follows. The t^{h17} chromosome was derived by Mary Lyon⁸. It carries *T*; t^{h17} , an isolated lethal factor derived from t^6 (t^6 complementation group); $+^{tf}$ and translocation 190 (T190) inseparably linked to the lethal factor. *Trans* to wild type, it allows recombination in the region of homozygous wild-type chromatin between *T* and t^{h17} which we measure in males as 16.6% (193/1,161) between *T* and *tf*. This agrees well with Lyon's figure of 18.1% for males and females⁶. The $t^{w12}tf$ chromosome is a complete lethal haplotype containing t^7 (the mutant tail interaction factor), t^{w12} lethal factor (t^{w1} complementation group) and *tf*. The *tf* on this chromosome appeared spontaneously either as a point mutation or small deletion; recombination was not involved because the t^{w12} chromosome still retains its original H-2 type (Craig Hammerberg, unpublished data). We maintained the $t^{w12}tf$ chromosome in the balanced lethal cross ($Ttf/t^{w12}tf \times Ttf/t^{w12}tf$) homozygous for *tf* and thus the recombination rate is difficult to estimate accurately (see Table 1, line 2). However, recombination from the parental $t^{w12}+$ chromosome where the exchange of tufted can be monitored is 4.4×10^{-3} (24/5,576) (see Table 1, line 3). Taken together, the recombination rate between *T* and *tf* in the presence of $t^{w12}tf$ or $t^{w12}+$ is $<0.5\%$.

In choosing the two haplotypes t^{h17} and $t^{w12}tf$, we also took into consideration the fact that they share the same H-2 type, as this suggests that the two chromosomes may have a common descent from a single ancestral *t*-haplotype by mutation, and thus that their abnormal chromatins would be homologous.

Recombination measured in $t^{h17}/t^{w12}tf$ females was an extremely high 18.4% (Table 1, last cross). This is remarkably close to the value of 17–18% for t^{h17} *trans* to wild type, and high for the interval *T*-*tf*. Clearly, recombination is occurring freely between the t^{h17} and $t^{w12}tf$ chromosomes.

Of the 14 recombinant chromosomes obtained, 7 have so far been analysed. The important question was whether the two reciprocal types of recombinants, short-tailed tufted (*Ttf*) and normal-tailed non-tufted ($t^T + ^{tf}$ T190) carried one, or both, or

Fig. 1 Situations in which Mary Lyon measured recombination; diagrammed after Lyon *et al.*^{6,8}. *T*, the region of the Brachyury mutation (*T*), and the tail interacting factor (t^T) present in complete lethal *t*-haplotypes. *A*, as denoted by Lyon, the region of a ratio factor. *LS*, the region of lethality and sterility factor (*s*) is also the region where the marker tufted (*tf*) maps. *a*, Recombination between chromosomes with a short overlapping region of *t*-chromatin; *b*, recombination in haplotypes thought to be non-overlapping.

* Present address: Cold Spring Harbor Laboratory, Cold Spring Harbor, New York 11724, USA.

Table 1 Recombination data for T - tf interval in t^{h17} and t^{w12} mice

Cross	Normal tailed tufted	Normal tailed non-tufted	Short tailed tufted	Short tailed non-tufted	Tailless tufted	Tailless non-tufted	Recombination rate (%)
$\delta Tt^{h17}T190 +^{tf}/++ \times \delta +/++ \times tf/++ \times tf$	405	94*	99*	563	NE	NE	16.6†
$\delta Tt^{w12}tf \times \delta Tt^{w12}tf$	NE	16*	NE	NE	6,682	NE	0.24
$\delta Tt^{w12} +^{tf} \times \delta Tt^{w12} +^{tf}$	NE	20*	NE	NE	4.5‡	5,576	0.44
$\delta Tt^{h17}T190 +^{tf}/t^{w12}tf \delta +/++ \times tf/++ \times tf$	27	7*	7*	35	NE	NE	18.4

Mice were scored for tail length at birth and for tufted at 28 ± 2 days. The second and third group of crosses are balanced lethals where, in the absence of recombination, the only expected phenotype at birth is tailless; T/T and t^{w12}/t^{w12} embryos die before birth. All the normal tailed mice born were genetically analysed for their recombinant chromosome. Those that were fertile all proved to be $t^{w12}/t^{viable}tf$, that is carrying the proximal end of t^{w12} haplotype with the tail interaction factor but having lost the distal lethal component. The tailless tufted mice in the third cross represent the same class of recombinant but heterozygous with $T(Tt/t^{viable}tf)$. The reciprocal recombinant, $Tt^{lethal}+$, presumably goes undetected in this cross because it cannot meet a chromosome with which it is viable. NE, not expected.

* Recombinant phenotypes in each cross.

† The numbers in this cross include previously unpublished data of L. C. Dunn and D. Bennett, 1965–1973, and current data up to 1979.

‡ The 4.5 tailless tufted is a projected number based on one tailless tufted out of 1,242 tailless mice that were raised and scored for tufted.

Table 2 Analysis of new recombinant haplotypes

Haplotype	Cross	Complementation data			Recombination data				Rate (%)
		Normal tail	Short tail	Tailless	Normal tailed non-tufted	Normal tailed tufted*	Short tailed non-tufted*	Short tailed tf	
$Tt^{s1}tf$	$\frac{Tt^{s1}}{++} \times \frac{++}{Tt^0}$	83	33	12	7	0	1	8	6.3
	$\frac{Tt^{s1}}{++} \times \frac{++}{t^{w12}}$	142	23	2†					
$Tt^{s5}tf$	$\times t^{0+}$	28	36	11	21	3	5	75	7.7
	$\times t^{w12}$	21	28	0					
Tt^{s6}	$\times t^0$	12	26	16	37	1	2	54	6.1
	$\times t^{w12}$	11	29	0					
Tt^{s10}	$\times t^0$	12	6	3	41	4	6	84	7.4
	$\times t^{w12}$	27	0	0					
Tt^{s11}	$\times t^0$	15	35	14	31	5	4	54	9.6
	$\times t^{w12}$	95	15	2†					
$t^{s8}T190$	$\frac{T}{t^0} \times \frac{T}{t^0}$	0	NE	17			No data		
$t^{s8}T190$	$\frac{T}{t^{w12}} \times \frac{T}{t^{w12}}$	3	NE	2					
$t^{s9}+$	$\times t^0$		No data				No data		
	$\times t^{w12}$	5	NE	2					

The new recombinant haplotypes were arbitrarily designated $t^{s1,s2}$ and so on in order of their detection. For the complementation data, the numbers at birth contain pooled male and female data (except for $Tt^{s10} \times t^{w12}$) and are usually distorted reflecting the male ratio. Recombination data are obtained from crosses of $Tt^{s1}tf/++ \times +/++ \times tf/++$. Data are pooled reciprocal crosses except in the case of Tt^{s11} where the data are from females only. The numbers scored reflect preferential culling at birth against normal tails. NE, not expected.

* Recombinant phenotypes.

† This class in Tt^{s1} and Tt^{s11} are recombinants; three tested as recombinants, one never bred.

‡ Same as for t^{s1} crosses above.

neither of the lethal factors present on the parental chromosomes. The complementation data shown in Table 2 demonstrate that all five Tt^{s1} recombinants analysed carry the t^{w12} but not the t^{h17} lethal factor.

The data for the $t^{s1} +^{tf}$ T190 recombinants are still sparse, as the T190 translocation renders them semi-sterile, and difficult to analyse in complementation tests. Nevertheless, available data (Table 2) suggest that this class contains the t^{h17} lethal factor but not t^{w12} . At face value these data suggest that t^{w12} and t^{h17} act as alleles. However, three alternative and equally likely interpretations must be considered. First, t^{w12} and t^{h17} may be very closely linked, and only the analysis of many recombinants could define them as genetically separate. Second, all the recombination may be taking place in a restricted 'hot spot' to the left of both t^{w12} and t^{h17} . There is some evidence from exceptional recombination in mice heterozygous for t -chromatin that the second possibility is true. In eight exceptional recombinants from balanced lethal stocks containing various complete t -haplotypes and also an interstitial marker qk between T and tf ($T(3)qk(4)tf$), all eight cross-overs were between qk and the t

lethal factor (K.A., unpublished data). In the present study another marker ($Tcp-1$), known to be between qk and the t lethal factor⁹, was monitored; 10/10 recombinant chromosomes tested resulted from cross-overs between $Tcp-1$ and t^{lethal} . A third, obvious possibility is that the lethal factors are actually located distal to $tufted$, and as we screen for recombinants using $tufted$, they will always be exchanged.

Recombination data for the new haplotypes $Tt^{s1,s5,s6,s10,s11}$ (all of the $Tt^{w12}tf$ type) are also presented in Table 2. Clearly they now all allow recombination, just as the parental haplotype t^{h17} does, in the region of homozygous wild-type chromatin between the centromere and the t^{w12} lethal factor. All nine such recombinants tested were between T and t^{w12} . Recombination in these heterozygotes, however, is about 8–11%, considerably less than that from the Tt^{h17} T190 chromosome; this supports the suggestion of Lyon⁶ that the very high recombination in the translocation heterozygotes was produced by the translocation itself.

The transmission ratio data for the various recombinant haplotypes are given in Table 3. Clearly the Tt^{s1} chromosomes

Fig. 2 Construction scheme of compound heterozygotes for t^{h17} and $t^{w12}tf$ and their expected offspring when mated to normal tail tufted. Short-tailed t^{h17} carriers were mated to tailless $t^{w12}tf$ mice. The tailless offspring, which are $Tt^{h17}/t^{w12}tf$, were selected. Males were tested for fertility. 4/4 were sterile, as expected, because they carried two complementing lethal factors. Females were mated to normal tailed tufted homozygotes to observe recombination between T and tf . Parental types: short tail, non-tufted, T190, and normal tail, tufted. Recombinant types: short tail, tufted, and normal tail, non-tufted, T190.

have a generally high, but very variable, ratio whereas the reciprocal type have very high and quite invariant ratios. For comparison note that the parent $t^{w12}tf$ chromosome is also transmitted in very high proportion (the last six males of this type we have tested with progeny samples over 25 averaged 98% t -bearing offspring), with individual male ratios of 100, 100, 100, 99, 96 and 87% respectively. The parent Tt^{h17} chromosome, on the other hand, in similar samples, gave an average ratio of 65%, and individual males were more variable, having ratios of 76, 73, 73, 72, 61 and 42%. Thus, recombination between the $t^{w12}tf$ and Tt^{h17} chromosomes has altered the transmission ratio characteristic of the respective lethal factors, implying that some element(s), such as the 'A' factor predicted by Lyon¹⁰ to lie between T and t^{lethal} , has been switched by recombination. This explanation does not completely account for the data, however, as the Tt recombinant ratios are both generally higher and more variable from male to

male than those typical of Tt^{h17} . Further work on interactions between A factors and specific t -lethal factors will be necessary.

The possibility remained that the translocation inextricably associated with t^{h17} was in some mysterious way responsible for overcoming the recombination suppression of the complete t -haplotype $t^{w12}tf$. Preliminary data rule out the presence of T190 as a factor in overcoming the suppression: one of the chromosomes derived from the above cross, $Tt^{h17}tf$, genetically analysed to be $Tt^{w12}tf$ and now devoid of T190, was set up *trans* with the complete haplotypes $t^{w5}+$ and $t^{w32}+$. Recombination scored so far in these compound females is 2/25 for t^{w5} and 6/33 for t^{w32} , demonstrating that the presence of the translocation is not required for recombination.

We set out to test the hypothesis that recombination in t -haplotype/wild-type heterozygotes is impaired because of mismatching between normal chromatin and abnormal t -chromatin. In fact, as all t -haplotypes are thought to be derived from a common ancestral haplotype¹¹ with divergences due to mutation in recombinationally isolated chromatin, whatever is wrong with the DNA in one t -haplotype should be matchingly wrong in complementing but mutant t -DNA. Thus, it is not unreasonable that variant t -DNA should recombine with variant t -DNA. Therefore crossing-over should occur in long regions of homozygous abnormal t -chromatin. Our data show unequivocally that recombination suppression is indeed abrogated in such combinations. We conclude that recombination suppression is not due to some intrinsic inability of t -chromatin to undergo crossing-over. An alternative hypothesis suggested above and consistent with the data is that mismatching between normal and variant chromatins is responsible. DNA cloning should show whether the non-coding sequences of t -DNA are rearranged or scrambled with respect to wild type.

All the recombination events we measured occurred in a restricted region proximal to the tf marker. Our experimental design, which used two different t -haplotypes with the same $H-2$ haplotype, precluded studying recombination distal to *tufted*. Nevertheless, it is important to know that recombination suppression associated with t -haplotypes can be circumvented, and the use of second-generation recombinants with different $H-2$ types will make possible dissection of the t -region identifying the number of genes involved, and mapping them with respect to one another.

K.A. thanks Drs Dorothea Bennett and Paulette McCormick for valuable suggestions. This work was supported by grants from the NIH.

Table 3 Transmission ratio of recombinant haplotypes

Haplotype	Male no.	Total informative offspring	% Of offspring carrying Tt or t -haplotype (ratio)
Tt^{s1}	1, 2	155	44
	3	127	28
Total		282	37
Tt^{s5}	1	63	64
	2, 3, 4	91	67
	5, 6	67	88
Total		221	72
Tt^{s6}	1	60	95
	2	119	89
	3	76	70
Total		255	84
Tt^{s10}	1, 2	110	51
	3	67	69
	4, 5, 6	88	69
	7	78	100
Total		343	70
Tt^{s11}	1	92	79
	2	69	35
Total		161	60
t^{s2}	1-2	9	100
t^{s3}	1-2	15	100
t^{s8}	1-7	146	88
t^{s9}	1-2	25	84
t^{s12}	1-6	83	84

Transmission ratio was measured in Tt haplotypes by mating $Tt/++$ males to $+/+$ females and scoring tails at birth. The ratio of Tt is calculated as short tail/total mice born. Occasionally the ratio of two or three brothers was measured collectively. The ratio of t -haplotypes was measured in two ways. First, $+/t$ males were mated to $T/+$ females, where the measure of the male ratio is tailless/short tailed plus tailless, as the normal tails are noninformative. Second, T/t males were mated to $+/+$ females and the ratio calculated as normal tail/total mice born. The data for the t -haplotypes are pooled within a haplotype because the numbers are scant because of semi-sterility due to the presence of T190.

BOOK REVIEWS

Séveso: the intrigue and the infighting

Alastair Hay

THE message of *The Superpoison* is both powerful and moving. The third book on dioxin to have been published recently, it covers ground similar to a previous one by Thomas Whiteside (for review see *Nature* 283, 229; 1980). Margerison, Wallace and Hallenstein, however, are specifically interested in the effects of dioxin on the residents of Séveso. This small Italian town fifteen miles north of Milan was contaminated by the inadvertent discharge of 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (dioxin) when a reactor manufacturing 2, 4, 5-trichlorophenol overheated. Margerison *et al.* have written a well researched book on Séveso which deals with the subject at every level: human, scientific and political. Like Whiteside, they show that the Séveso residents were pawns caught in a process which rapidly lost its human element.

Confusion became a fact of life for the people in Séveso and the surrounding towns. Some leading scientists warned residents that dioxin was extremely dangerous; others, of equal repute, claimed there was no hazard. As the authors point out even the Catholic Church had to have its say. This was particularly true on the question of abortion brought into focus by the teratogenic properties of dioxin. When women, pregnant at the time of the reactor accident, were warned that exposure to dioxin might cause them to give birth to malformed children, the Vatican newspaper *Osservatore Romano* declared: "Is the mere possibility of the risk of malformation a sufficient reason to eliminate an unborn human being which undoubtedly has a greater chance of being born normal than abnormal?". Cardinal Colombo, Archbishop of Milan, joined the argument, according to Margerison and his co-authors, "by praising certain couples who had volunteered to adopt any malformed children born in the Séveso area, and appealing for others to come forward".

In the opinion of the authors it was the pregnant women from Séveso who had the most harrowing time. They claim that it was not only the church and politicians of a right-wing persuasion that made life difficult for the women, but that the Left were equally guilty in this regard, manipulating the situation at Séveso to advance their cause for abortion law reform in Italy. The campaign to reform the law and make abortion easier was

The Superpoison. By T. Margerison, M. Wallace and D. Hallenstein. Pp.236. (Macmillan, London: 1981.) £7.95.

eventually successful, but action came too late to help the women of Séveso. For many, the risk of having a malformed child was too great. The government claimed that in such cases abortion was legally available in Italy, the law making adequate provision. The reality was quite different. Most doctors refused to terminate pregnancies, subjecting the women to humiliating treatment. In the end only 34 pregnancies were terminated legally. At least twice that number are said to have been performed either abroad or illegally in Italy.

Controversy still rages in Italy over the effects of dioxin on the children born to mothers who decided against abortions. Three sources — the Italian Parliamentary Commission report on Séveso, the former head of the Health and Epidemiology Commission for Séveso, Professor Gaetano Fara, and Dr Guiseppi Reggiani, Director of Medical Research for Hoffmann-La Roche — all claim that there is no increase in the rate of malformation in the children born in Séveso. The authors of *The Superpoison* are not convinced. Acknowledging that the lack of statistics for malformation rates in Italy as a whole makes difficult the interpretation of the situation at Séveso, they nevertheless feel that there is "cause for serious concern".

Their concern is based on claims made by a local general practitioner working in Séveso. According to Alberto Colombi and the People's Scientific and Technical Committee — a largely left-wing association of doctors and scientists — there is gross under-reportage of the number of malformations. It is certainly true that the number of abnormalities is higher than official figures would suggest. The reason for their exclusion from published statistics, however, is explicable. Many of the malformations are minor. Their inclusion, although increasing the total number of cases, still does not alter the general pattern. Whichever set of figures is chosen and compared with the norm for various regions of Italy or with other countries in Western Europe, the answer is the same:

the rate for Séveso does not appear to be higher than anywhere else. However, research in progress may alter this conclusion.

The authors make much of the differences in the published figures for the number of cases of chloracne — the disfiguring skin disease caused by dioxin. In their view, "with so much disagreement between published figures, it is difficult to have confidence in the statistics" for the number of cases of chloracne observed. Again, the authors believe that the authorities are underestimating the seriousness of the situation and they cite various local doctors to support this charge. One such, the local Séveso health officer, Dr Francesco Uberti, is quoted as saying that he found 150 cases in children at one school alone. Uberti claims that the Milan regional authorities denied that his cases were genuine chloracne and "manipulated the facts". Diagnosis of chloracne can be difficult, as the authors admit, and this is at the basis of the disagreements about incidence. But this book was prepared some time ago, and the situation is now much clearer. A final figure for the total number of children who contracted chloracne has been agreed; it is 187.

Disagreements about the actions taken by the local authorities to protect the population at Séveso are well known. Margerison *et al.* insist that Givaudan and Hoffmann-La Roche, the principal companies involved in the dioxin problem, were aware of the dangers facing the residents of Séveso. They are unimpressed by the companies' arguments that it took time to construct a map of dioxin contamination preparatory to evacuating a section of the Séveso population. Indeed, they imply that the companies convinced the Italian authorities that the situation at Séveso was not dangerous. Two weeks after the dioxin discharge from the reactor, the authorities were indeed claiming that an evacuation was unnecessary. According to the authors, this complacency was shattered when Roche's Director of Medical Research insisted that an evacuation was absolutely essential. Many of these facts are not in dispute; however, the authors' thesis that the authorities were lulled into a sense of false security by Givaudan and Roche only to be caught out by Roche later on is not really proven.

All three authors are professional

journalists. Tom Margerison is a well known science journalist and this book has benefited from his skills. Technical details essential to the arguments are put clearly and simply. The operation of the trichlorophenol reactor at Séveso is well described. Accounts on the operation of the reactor differ, say the authors, depending on whether it is the workers themselves describing the operation or the management describing the instructions given to the workforce.

No satisfactory explanation is available yet to explain why the accident occurred. The authors find attractive a theory that there may have been sabotage. They say that one piece of evidence supports this. The reactor contents at Séveso are not alkaline as might have been expected. It is as though they were neutralized with acid, say the authors, giving credence to the sabotage theory. They do admit, however, that the pH change may be attributable to temperature differences, as indeed it is. Experiments designed to re-create the conditions in the Séveso reactor have since shown that at temperatures in excess of 260°C the pH of the contents changes from

alkaline to acid. The temperature of the reactor at Séveso is thought to have reached at least 350°C. Sabotage is ruled out in this case.

Political intrigue was rife at Séveso and this book describes it in ample detail. Scientific infighting also occurred and the authors take many irreverent swipes at the various experts involved with the dioxin problem. Interviews with many of the Séveso residents confirm that their treatment by the various authorities has been high handed. The authors succeed in showing that the residents at Séveso have had a raw deal. In their view the final immorality of the whole episode was that "Hoffmann-La Roche had the benefit of a profitable product while the innocent citizens of Séveso unknowingly took the risk". This may well be the verdict of history. But as more information accrues it is clear that the issue is not as clear cut as the authors make out. The companies certainly have much to answer for, but so too do the Italian authorities. □

More from Harris

Alan E.H. Emery

The Principles of Human Biochemical Genetics. By Harry Harris. 3rd Edn. Pp.558. (Elsevier/North Holland Biomedical: 1980.) Hbk \$65.75, Dfl.135; pbk £26.75, Dfl.55.

THE first edition of this book, published in 1959, was an immediate success. The subject of human biochemical genetics was then in its infancy but there were sufficient pointers to indicate the exciting possibilities for the future. It has to be remembered that until Garrod introduced the idea of inherited disorders involving chemical processes (so-called inborn errors of metabolism) at the turn of the century, human genetics had been largely concerned with the inheritance of obvious structural abnormalities. In 1923 Garrod was only able to describe some half-dozen rare inborn errors of metabolism, but now Professor Harris details some 120 such disorders and a further 73 enzyme and protein polymorphisms.

This new edition is divided into nine chapters with an appendix listing details of specific enzyme deficiency disorders, and a similar appendix of enzyme and protein polymorphisms. The introductory chapter on gene mutations and single amino acid substitutions is, like the rest of the book, a model of clarity and could well form the basis of any graduate course in genetics. Genes can no longer be considered merely discrete sections of DNA contiguous with each other, but are frequently separated by intervening sequences where the relevant messenger RNA is not translated into protein. The function of these intervening sequences is as yet not clear, but in the future the unravelling of their role in gene action could well herald yet another new departure in biochemical genetics.

Two chapters are devoted to the principles of gene action which are largely, though not exclusively, illustrated from findings in the haemoglobinopathies. A discussion of gene localization (mapping) is also included. Until recently gene localization was dependent on the study of pedigree and somatic cell hybrids, but is now being greatly helped by the use of restriction endonucleases. In the near future this, too, is going to generate an entirely new perspective of gene structure and localization.

Subsequent chapters also deal with quantitative and qualitative variations in enzymes, inborn errors of metabolism and blood group substances. However many enzyme and protein variations (and the more recently discovered variations at the DNA level of restriction endonuclease cleavage sites) appear to be unrelated to any specific disorder, yet often their incidence is far greater than could be accounted for by mutation alone. Harris suggests that the term polymorphism might be reserved for those variations in which

Plasma physics for robust readers

A.D.R. Phelps

Plasma Physics for Nuclear Fusion. By Kenro Miyamoto. Pp.610. (MIT Press: 1980.) £35, \$50. *Fundamentals of Plasma Physics.* By V.E. Golant, A.P. Zhilinsky and I.E. Sakharov. Pp.405. (Wiley-Interscience: 1980.) £22.10, \$51.90.

BOTH of these books treat several aspects of plasma physics in detail, and yet neither provides a complete coverage of the subject — Golant *et al.* intentionally omit the important subject of waves in plasmas and Miyamoto, as implied by his title, concentrates on those topics in plasma physics which relate to nuclear fusion. Both are appropriate for postgraduate courses, and should appeal particularly to the mature research scientist.

The text by Miyamoto uses rationalized mks units and is a translation of his 1976 Japanese publication. Some opportunity appears to have been taken to update a few of the references, but some of the most recent results of nuclear fusion research have not been included. Nevertheless, much of the content has not hitherto existed in such digestible textbook form.

Professor Miyamoto divides his 16 chapters into four sections: fundamentals, which includes a review of fusion criteria, magnetic field configurations, single particle motion, Coulomb collisions and kinetic equations; MHD, covering equilibrium, diffusion and confinement, and instabilities; kinetic description of waves and instabilities, which treats waves

in cold and hot plasmas and velocity space instabilities; and finally, heating, diagnostics and confinement.

Fundamentals of Plasma Physics is also a translation (from the original 1977 Russian edition) and, like Miyamoto's book, more readable than might be expected. In ten chapters the authors cover collisions, kinetic equations, equilibrium plasmas, distribution functions, transport processes and magnetic field influences on particle motion, transport processes and plasma confinement. Cgs units are used. The notation is somewhat inconsistent in places, for example rot and curl appear on the same page and the Laplacian operator used in the text does not correspond to that given in the symbols list. Yet these are minor points which should not worry the relatively robust reader for whom both books are best suited.

Whereas Miyamoto's book essentially involves the high temperature collisionless type of plasma, Golant *et al.* address themselves more to gas discharges and ionization phenomena. Although there is some overlap in subject matter between the two books, the difference in emphasis makes them complementary. Thus one might expect the libraries of those research laboratories and universities engaged in plasma physics research to invest in both of them. □

A.D.R. Phelps is a Lecturer in Natural Philosophy at the University of Strathclyde.

the commonest identifiable allele has a frequency no greater than 0.99 and therefore the proportion of heterozygotes is at least two per cent of the population. It is difficult to account for the high prevalence of such polymorphisms and the author presents a very readable account of the problem. It might, of course, turn out that most of these variations are no more than "random noise", but it is difficult to accept that this could be the entire explanation.

Altogether this is a fine book which can be unreservedly recommended as a graduate student text as well as a work of

reference. Of course, because of the enormous growth of the subject, this new edition might now appeal more to the specialist. Perhaps for a more general readership Professor Harris could be persuaded to produce a basic text similar to his *Introduction to Human Biochemical Genetics* which was published some 22 years ago by Cambridge University Press and which was the progenitor of the current text. □

Alan E.H. Emery is Professor of Human Genetics in the Medical School of Edinburgh University.

Where psychology meets biology

M. J. Morgan

Essay on Mind. By D. O. Hebb. Pp.159. (Lawrence Erlbaum Associates: 1980.) \$16.50.

IN THIS "essay", Professor Hebb expresses in clear and forceful language his conviction that "... mind and thought, consciousness and creativity and free will, are all biologically evident phenomena and seen most clearly in the light of evolutionary ideas". He summarizes the historical development of his own "cell assembly" theory, familiar from his classic book *The Organization of Behaviour* (Wiley, 1949) and to a certain extent attempts to relate it to modern developments in neurophysiology and psychology. There is little here that is very new, but Hebb was one of the first to argue that psychology is largely a biological subject, at a time when it was neither profitable nor popular. The gritty style of this book makes few concessions to the subtleties of professional philosophy, and somehow manages to convey the general impression that objections would be unwise and ill-informed, if not actually silly. Fortunately, no one need feel too offended by this brusque treatment, because the counter-arguments are put into the mouths of anonymous "writers", rather than being attributed to specific people.

On the heredity-environment issue Hebb neatly clears up some common confusions, and expresses the view that extreme environmentalism can have morally dangerous effects. It is pleasing to see the boot on the other foot for a change: usually it is environmentalists who assume the mantle of moral superiority. Returning to a theme familiar from his *Textbook* (W. B. Saunders, 1972) Hebb warns the young student that if he has an inherited predisposition to alcoholism, he had better recognize it quickly and take appropriate avoiding action. This he is not likely to do "... if he takes it for granted that all men are born equal ... and seeing others drink freely without becoming drunks,

takes it for granted that he can do the same". This is probably good advice, certainly no worse than that given by people who think that it is wicked to believe in genes.

The "cell-assembly" model can now be seen as one of the first "feature analysis" models of perception. Its essence is that cells or groups of cells coding for distinctive features such as lines are grouped together into superordinate assemblies by associative learning. These assemblies can in turn be grouped into assemblies representing concepts, and so on, presumably up to "grandmother assemblies", which would be activated when we were thinking of a particular person. Hebb notes that the physiological work of Hubel and Wiesel has given considerable support to this idea since he first produced it, but he quotes their hierarchical model as if it were established fact, without mentioning important criticisms. He also attempts to extend the theory in a way that many readers will probably find frankly metaphorical: we read, for example, that "Emotion is a disruption of cell assemblies".

The experiments that Hebb pioneered at McGill on effects of early environment in animals are given prominence and still raise issues of great interest. But as in the case of the discussions of visual perception, it is disappointing not to be presented with any more recent data, particularly those concerning effects of early environment on synaptic connections.

Possibly the most interesting aspect of this book is the historical insight it gives into the process by which Hebb arrived at his theory at a time when radical behaviourism made any physiological theorizing disreputable. That many of these early battles will now seem a bit outdated to the younger generation of psychologists is a measure of Hebb's success in helping to win them. □

Comparative Biology and Evolutionary Relationships of Tree Shrews. Edited by W.P. Luckett. Pp.314. (Plenum: 1980.) \$39.50, £24.89.

TREE shrews are placental mammals of Southeast Asia. Although not rodents, they resemble squirrels and the Malay word "tupai" is used for both. Of all placental mammals, tree shrews are probably the most enigmatic and differences of opinion concerning their evolutionary relationships

The pen-tailed tree shrew, *Ptilocercus lowii*, from the plate in the original description by J.E. Gray.

have caused some heated exchanges among mammalogists. Originally included in that ragbag of an order, Insectivora (within which they had been particularly allied with the elephant shrews of Africa), the tree shrews came to be widely regarded as the least-specialized grade of primate largely as a result of the work of Alberta Carlsson and W. E. Le Gros Clark. In this volume there are contributions on the tree shrew skeleton, dentition and cranial circulation, their meagre fossil record, their nervous and reproductive systems, and the molecular evidence for their relationships. Behavioural studies on tree shrews are not represented: distinguished work in this area has already been published, but Luckett implies that it has little to contribute to solving the problem of tree shrew relationships.

Contributors to the volume were asked to consider two questions in their accounts: first, do tree shrews and primates share unique derived characters suggesting an immediate common ancestry; second, are there reasons for supposing that tree shrews, primates, bats and colugos ("flying lemurs") together form a discrete evolutionary group (Archonta) amongst mammals?

It was part of the message from the work

of Van Valen and of Martin in the late 1960s that progress in assessing the evolutionary affinities of the tree shrews and other problematic groups, collected together in the past as Insectivora, would be made only if comparisons were made between these animals and all other mammalian orders. However, if Luckett had insisted on such application from all his authors, several of them would have been consigned to a lifetime's work.

The fascination of tree shrews reaches beyond biologists interested in Insectivora (in the widest sense) to include those concerned with the principles of phylogenetic reconstruction. In his introductory chapter, Luckett succinctly summarizes the phylogenetic methods described by Hennig, and uses them to dispose of the early arguments for immediate common ancestry shared by tree shrews and elephant shrews. Particular emphasis is given to the reconstruction of the primitive state for various characters in the hypothetical eutherian common

ancestor. In reviewing the evidence of all the contributors, Luckett reaffirms Butler's and McDowell's concept of the isolation of both the tree shrews and the elephant shrews, leaving other Insectivora as an assemblage of animals which may have some claim to monophyly.

It is hardly surprising that there are few firm conclusions concerning the relationships of the tree shrews, although Szalay and Drawhorn reassert the validity of Archonta, a tactic supported in varying degrees by the two chapters on molecular evidence. Inevitably, much recent work on tree shrews has been inconclusive, even destructive, but this might be viewed as a clearing of the decks. In any case, a volume that includes several chapters of thoroughly admirable compilation and evaluation of morphological data is very welcome for that alone. □

Adrian Friday is Assistant Curator of Vertebrates at the University Museum of Zoology, Cambridge, UK.

Pedagogical overview of quantum fields

Paul Davies

Quantum Field Theory. By Claude Itzykson and Jean-Bernard Zuber. Pp.700. (McGraw-Hill: 1980.) £26.95, \$55.50.

A NEW generation of textbooks on quantum field theory is appearing, and this monumental work of 700 pages promises to become the standard book to replace Schweber's *An Introduction to Relativistic Quantum Field Theory* (Harper & Row, 1961), or Bjorken and Drell's *Relativistic Quantum Mechanics* (McGraw Hill, 1964) and *Relativistic Quantum Fields* (McGraw Hill, 1965), both nearly 20 years old. The subject has moved a long way in that time, and a comprehensive, pedagogical book covering both the traditional material and modern developments is long overdue.

The authors have been lavish and ambitious in their approach. Starting with classical field theory, they build upon an extensive discussion of the Dirac equation towards a thorough treatment of conventional quantum electrodynamics. On the way, all the mathematical formalism needed for the more familiar applications is presented. Also included are some topics that are generally hard to find in textbooks: the Klein paradox, the Heisenberg-Euler effective action, the Fock-Schwinger proper time method, finite temperature states, massive vector fields and the Casimir vacuum force effect. Especially welcome are the treatments of symmetries, the PCT and spin-statistics theorems, and a section on Grassmann algebra.

All the routine machinery of interacting

relativistic quantum fields then emerge via the S-matrix and Feynman rules, with extensive applications to quantum electrodynamic processes on the way. Then, on through dispersion relations and analyticity to an extensive section on radiative corrections and renormalization theory. Once again, one welcomes the inclusion of modern topics like Wick rotation, asymptotic behaviour and dimensional regularization.

But all this comprises only the first half of the book! The really attractive feature is the comprehensive treatment of recent functional methods, gauge theories and asymptotics which occupies the last 300 pages. An extensive discussion of non-Abelian gauge fields and spontaneous symmetry breaking opens the way to topics such as the Weinberg-Salam theory, anomalies, Fadeev-Popov ghosts and scaling behaviour in scattering theory.

This valuable survey is written with meticulous care and thoroughness. Although intended primarily for graduate students, there is such a wealth of material that undergraduates will find it useful for reference. Those learning relativistic quantum mechanics will also benefit from the chapter on the Dirac equation, hole theory and hydrogen-like atoms. Certainly, any student of quantum field theory will find everything necessary for a thorough grounding in this increasingly important subject. □

Paul Davies is Professor of Theoretical Physics at the University of Newcastle upon Tyne.

12 March 1981

How true is the theory of evolution?

So is Darwin's theory of evolution a fact, a pack of lies or something in between? This is the question prompted by the two letters with which the British Museum (Natural History) has broken its long silence over the rights and wrongs of cladistics and other matters (see page 82). That this issue has burst into the open in the same week as the trial in California of the suit by the Creation-Science Research Center of San Diego against the Californian State Board of Education is both ironical and apt. In California, the creationists are complaining that the theory of evolution is being taught as if it were a fact, and that the constitutional rights of Californian schoolchildren are thereby being infringed. The correspondents from the Natural History Museum complain that a leading article in *Nature* two weeks ago implied that the theory of evolution is a fact. Both sets of complainants deserve to be taken seriously, the people from the museum more seriously than the creationists. Both are mistaken.

The question they have separately raised is, nevertheless, interesting and important. The theory of evolution is now more than a century old, and has been much transformed and modified during that long period. The objectives of the theory are what they always were, however — to account for the diversity of species as well as for their similarities and differences, and also to account for the evidence of the fossil record, which suggests changes in the patterns of living things in the course of time. It is acknowledged that this apparently innocuous statement begs one question which some consider to be important. The word *species* implies that species exist. Some out-and-out cladists prefer to avoid this assumption. Many of the differences between apparently mutually infertile groups of plants or animals may, the cladists say, be differences of degree and not of kind. Although this issue may be important in its own right, it is not strictly relevant to the status of evolution as a theory. Cladistics, a technique of classification, is in no sense inconsistent with the theory of evolution. Indeed, on the face of things, cladistic systems of classification should be more easily accommodated with the theory of evolution than those based on species. Cladism, therefore, is irrelevant to this journal's quarrel with the Natural History Museum, at least as now defined.

Another begged question lies in the word *evolution*. It is widely agreed that the fossil record implies substantial changes from one time to another in the pattern of extant living things, but it is not self-evident that the relationship between one pattern and a later pattern is properly described as evolutionary. That term implies that the pattern of living things at any time is determined by the pattern of living things at any earlier time and by environmental influences in the interval. Technically, evolution is a stochastic process. Because the fossil record can be (and frequently has been) interpreted in different ways, it is important openly to acknowledge that the essence of Darwinism includes two propositions — first, that successive stages in the fossil record are indeed related to each other in an evolutionary fashion and, second, that the mechanism of the transition from one to another consists of natural selection. So much even the creationists accept. It is not the content but the status of Darwinism that is now disputed.

But is not the theory of evolution simply a theory, a kind of glorified hypothesis that may be knocked down at any time, either because it is falsified or because a better theory comes along? This is what the round robin from the Natural History Museum asks. (The creationists, of course, go further.) The issue is complicated, and much confused by over-hasty readings of what Sir Karl

Popper has written on the significance of scientific theories as such. Theories are, of course, putative explanations of phenomena, or facts. Popper's great achievement, first of all stated in "The Logic of Scientific Discovery", was to point out that theories are not constructed by some non-existent logical process called "induction" but, rather, by the exercise of creative imagination. In the same important work, first published in 1934, Popper drew a sharp distinction between two kinds of theories — those which are capable of being falsified, for example by comparison with experiment, and those which cannot be thus falsified. Theories of the first kind, Popper says, belong properly to empirical science. Theories of the second kind, those which cannot be falsified, he called metaphysical. One obvious example of such a theory is that the world was made by God. Another is Darwinism.

Within the terms of the definitions he has helpfully constructed, Popper is technically correct. The course of supposed past evolution cannot be rerun. Nor is it possible to make predictions about the pattern of life-forms on the surface of the Earth that will be verifiable within the lifetime of people now alive. (Predictions that there may be fewer whales in the southern oceans some years from now are not tests of the theory of evolution but of the resolution of the International Whaling Commission.) Nevertheless, the theory of evolution is not entirely without empirical support. Dzhzhansky's classic work on the course of speciation among birds in Central America is a demonstration that, among one group of animals, the course of change is evolutionary, and that the mechanism is natural selection. Nevertheless, such demonstrations do not constitute a proof of Darwinism. They do not, for example, exclude Lamarckian processes or episodes of supernatural creation in past times. Darwinism is not the only theory afflicted by such problems. Cosmological theories are similarly incapable of falsification and are thus, in Popper's language, metaphysical. But metaphysical theories are not necessarily bad theories. Plainly it would be absurd if Popper's work were to be held to invalidate theories of evolution in general.

So how, in these circumstances, is it possible to tell the difference between good and bad theories? The first requirement of any theory, good or bad, is that it should be consistent with such phenomena as there are, and logically self-consistent. Darwinism is consistent with the data to which Darwin had access more than a century ago. One of the remarkable features of the theory is that it remains consistent with the vastly greater body of data now available. Yet Darwinism might have been falsified by any one of the host of discoveries of the past century. Although there is a certain randomness in the way in which palaeontological findings come to light, so that it is not possible to say that this current of discovery amounts to a stringent test of Darwinism, surely it is too wooden to insist on a strict interpretation of Popper's criterion for telling when a theory belongs to "empirical science" and when it is merely metaphysical. There is nothing in the letters from the Natural History Museum to suggest that the multitude of authors do not agree with that modest assertion.

On the grounds of internal consistency, Darwinism has also triumphed quite remarkably. In Darwin's time, the phylogenetic relationships between different living forms were inferred from their morphology. At the outset, it was entirely unforeseen that there would some day be more objective ways of constructing these relationships. Now, however, molecular biology has provided an independent (and potentially extremely powerful)

method of telling the relationships between species and groups of species, many of them only distantly related to each other. The result is a striking confirmation of the general character of the relationships suggested by Darwin and his contemporaries. To be sure, it is not possible to tell from a comparison of the structures of proteins found in primates whether people are more closely related to gorillas or chimpanzees, but that only goes to fill out Darwin's notion of divergent evolution from some common stock. At the same time, however, the quite remarkable constancy of some materials, the histone proteins for example, is vividly suggestive of the common origin of all living things, and of their persistence over time. Creationists would, of course, insist that none of this constitutes a proof of Darwinism in the strict sense. (If the histones are that special, God may have had no choice but to use them over and over again.) But the way in which the theory of evolution has been able to survive such a long succession of discoveries bearing on the mechanism of inheritance — the rediscovery of Mendelism, the discovery of chromosomes, the recognition of what genes are and the recognition that genes are usually pieces of double-stranded DNA — is striking evidence of its overwhelming consistency. No theory of such a grand scope in the physical sciences has done as well in the past century.

Logically, however, none of this amounts to proof. Popper, the creationists, the Natural History Museum and everybody else agree. It is also fair to acknowledge that there are matters on which a better agreement between theory and sketchy data is desirable. Much has been made of the episodic nature of the fossil record — the apparently long persistence of some species, the apparently sudden appearance or disappearance of others. If, however, the internal consistency of Darwinism cannot be counted as a proof, the supposed "gaps" in the fossil record, which may be a consequence of sampling bias of the kind that besets cosmology, cannot be counted as a disproof. It is also true that too little is known of the molecular structure of chromosomes (chromatin) for the mechanism of speciation to be fully understood. The time scale of supposed evolution is another supposed difficulty. How, the creationists ask, can the acme of evolution so far — the evolution of hominids — have been accomplished in a mere million years or so when it is supposed to have taken a thousand times as long to produce the first multicellular organisms? Honest Darwinists will reply that there are at present very few means of making quantitative calculations of this kind but they may also point to the way in which molecular biology is showing how a few genes may determine a surprising range of functions. In other words, there is no particular reason to suspect that outstanding problems of agreement between qualitative expectation and inadequate data will not in the end be accommodated. Creationists would naturally disagree. The Natural History Museum would probably have an open mind.

But what of the ways in which Darwinism may have to be amended? In the past few months, for example, the experiments of Gorgczynski and Steele (see *Nature* 19 February) have fanned excitement among the sceptics because they suggest that Lamarckian inheritance (acquired characteristics and all that) may be possible, in the laboratory if not in real life. So, if those experiments are confirmed, would Darwinism be dead? On strict logic, giving the two components of Darwinism (evolution and natural selection) equal weight, the answer would be yes. From a more practical point of view, the answer would take the form "it depends". If there turned out to be a well-defined set of circumstances in which Lamarckian inheritance occurred, and if these circumstances were in some sense exceptional, then the modification of Darwinism that would be required would be comparable with Einstein's modification (in special relativity) of Newtonian mechanics. "Darwinism is dead, long live Darwinism" would be the shout. And it is inconceivable that the circumstances could be other than exceptional — the regularity of the phylogenetic relationships revealed by molecular biology may not be a proof of Darwinism but they give the lie to Lamarckian inheritance as the engine of evolution. But even these considerations are for the time being irrelevant; the experiments concerned, which are capable of other than Lamarckian

interpretation, have not been confirmed. Most probably, the signatories of the letter from the museum would agree. Creationists would say that the argument is irrelevant.

Why, then, are the museum and *Nature*, both moderate institutions, at loggerheads? The leading article complained of did not ask that the theory of evolution "should be presented as fact" but protested at the use of the phrase "If the theory of evolution is true . . ." in a document intended for public circulation. The same article asked scornfully whether ". . . the theory of evolution is still an open question among serious biologists?" Two separate points arise, the first a matter of presentation. Knowing that large sections of the general public are sceptical of Darwinism, can it be sensible to use the phrase "If the theory of evolution is true . . ." when the museum's judgement is that there is "overwhelming circumstantial evidence" for Darwinism? To do so is to avoid challenging the sceptics when this is not merely possible but necessary. While some who doubt Darwinism do so on respectable grounds, others claim that the course of events may be determined by literally supernatural influences. Theories of that type are not even metaphysical — they are simply unscientific.

Nobody asks that the museum should declare a faith in Darwinism that would be unwarrantable but merely that it should choose its words more carefully. As the museum's brochure now reads, there is nothing to help the innocent reader to distinguish between alternatives to Darwinism such as the argument due to Hoyle and Wickramasinghe that the Earth has been repeatedly repopulated with living things (which is in principle a scientific theory, but for the time being metaphysical in Popper's sense) and entirely unscientific theories such as those of the creationists. It is mystifying that the museum should not have discovered this danger for itself. That is why the ambiguity of its public brochure is so shocking.

The second issue to which the museum needs to pay attention concerns its place within the professional community. The museum is a distinguished centre of scholarship. Given its interests, the museum's scholars are bound from time to time to be caught up in controversy. Its flirtation with cladism, although entirely proper and permissible, shows what passions can inflame those who look to the museum as a partner in research. Such troubles are unavoidable. On the evidence of the recent past, and to its credit, the museum has not been afraid to push its collective view that cladism is a valuable technique for classifying organisms. So why should it be so diffident in its approach to the grand theoretical issues? That Darwinism may ultimately be falsified is beyond dispute, but — if the round robin represents a collective view — the museum's ostentatious agnosticism on the subject is potentially dispiriting for the rest of us. If, in the museum's view, Darwinism is "seriously an open question" in the sense that some of the doubts about Darwinism raised in recent years are taken seriously, then it should take the lead in throwing light on these disputed issues. Who else? Yet there is no sign that the museum's research programme differs radically from what it has been in recent years.

The trouble with agnosticism is that, however well justified logically, it can be carried too far. If young scientists are brought up to believe that by their essence all theories are either falsifiable or metaphysical, is there not a serious risk that regard for the scientific enterprise as a means of understanding how the world is made will be undermined? Their elders are similarly seduced into the belief that, because nothing can be true, grubbing for data is all that matters. Whatever the philosophical position, there is no way of denying that people's emotions are engaged by the strengths and weaknesses of theories. To acknowledge that is not to acknowledge human frailty but simply (following Popper) that the construction of theories is a creative process, constrained only by conventions intended to suppress both speculation and prejudice. In all this, however, one prejudice is allowable, even necessary — the preconception that theories can be constructed to account for all observable phenomena. That is what the creationists cannot accept. It would have cleared the air if the signatories from the museum had said where they stood.

Mixed welcome for genes on Wall Street

Genentech's interferon from yeast plasmid

Washington

Anybody interested in following the progress of interferon research may soon find it easier to refer to the pages of the *Wall Street Journal* than to look in the scientific literature. Last week, shares in the West Coast genetic engineering company Genentech Inc. rose \$7, from \$36 to \$43, following the company's announcement that collaboration between Genentech and scientists at the University of Washington in Seattle had yielded interferon from genetically altered yeast cells. A few days earlier, shares in another publicly quoted company, Flow General, fell from 32 to 29½ cents with the news that the company faced delays in delivering the conventionally produced fibroblast interferon which it has agreed to supply to the National Cancer Institute for clinical trials.

The Genentech announcement was made during the First Annual Congress of Recombinant DNA Research, a privately sponsored meeting held in San Francisco. It represents the first public announcement of the successful use of yeast to produce mammalian proteins, although several other universities and companies are also working in the field and have yet to make their results known.

The techniques were developed by scientists in the University of Washington's genetics department, which has been studying the genetics of yeast since 1950. Dr Benjamin Hall, chairman of the department and one of the leaders of the research team, feels that the use of yeast could improve methods of producing interferon by up to a factor of ten.

Genentech has subsequently announced that it expects to be marketing interferon "before 1985". The company's vice-president, Mr Frederick Middleton, told a meeting of security analysts in San Francisco that the company's new human insulin, being developed with Eli Lilly and Co., would probably be on the market by the end of 1983. This would be followed within a year by human growth hormone, a bacterially produced version of which is now being tested on 20 children at the Great Ormond Street Hospital for Sick Children in London (see *Nature* 5 March, p.6).

Despite the long-term prospects, Mr Robert Swanson, the company's president, warned the analysts not to expect impressive performance figures from the company before it begins to market products. Citing the need for heavy investment in research and development,

as well as clinical trials, Mr Swanson said that in the next 12 to 24 months "it mightn't be possible to show a profit on a quarter-to-quarter basis".

In contrast to its bullish reaction to Genentech's news about interferon production, Wall Street responded less kindly to the announcement from Flow General that the first delivery of human fibroblast interferon to the National Cancer Institute would be delayed because of contamination problems with the cells.

The company's biomedical subsidiary, Flow Laboratories, has signed a contract with the institute to provide 50,000 million units of fibroblast interferon — enough for 50,000 doses — using a technique invented and patented by the Massachusetts Institute of Technology in which the interferon-producing cells are grown on the surface of small charged spheres. According to a report issued by the company, the viability of scaled-up production using the so-called "super-beads" was demonstrated in December. Since then, however, contamination of the cells has resulted in a "setback of an indeterminate period" which will delay the deliveries to the institute, due this month, by "some weeks".

The institute is already sponsoring

clinical trials at three centres using leukocyte interferon supplied by Meloy Laboratories of Springfield, Virginia, and at two centres with lymphoblast interferon produced by the Wellcome Foundation in London. It is also about to invite bids for the supply of gamma "immune" interferon for possible clinical trials, which has attractive properties distinct from the other more easily produced interferons. Flow General has reported that it is evaluating a process developed at New York University for the production of gamma interferon using conventional cell systems, to see if it would be able to produce sufficient quantities for further evaluation.

There is also evidence that the market's previous enthusiasm for genetic engineering stocks is waning. When the Berkeley-based Cetus Corporation went public last Friday, its shares opened at \$23, fell to a low of \$22½, and ended the day at \$23¼. Although this represented a record \$119 million initial public stock offering for a new company on Wall Street, Cetus's debut was much less spectacular than that of Genentech, whose shares soared from \$35 to \$80 on the first day of trading, but have since dropped back to near their original price.

David Dickson

Benefits and snags of yeast plasmids

Until Genentech and the University of Washington, Seattle, announced their success with interferon, there had been little news, most of it gloomy, about the chances of expressing mammalian genes in yeast rather than bacteria. And this despite the establishment of at least one company, Collaborative Research Inc., specifically to exploit yeast. A consultant for Collaborative Research said last week that part of the problem was simply that not enough was known about the basic molecular biology of yeast to make easy its subversion for unnatural purposes.

One important setback for the advocates of yeast occurred early on, when it was discovered that yeast could not cope with split genes. Most mammalian genes have their coding sequences interrupted by non-coding, or intervening, sequences. Bacterial genes are not split in that way and, not surprisingly, bacteria do not possess the mechanisms to decode the information encoded in split genes. The hope was that yeasts, more highly evolved than bacteria, might possess split genes and therefore be able to cope with mammalian split genes. But this has not proved to be the case. Indeed, the overriding reason for the successful expression of the human interferon gene in yeast is because it is that human rarity

— an unsplit gene.

Nevertheless, advocates of yeast still have reasons to be cheerful:

- Even split genes produce unsplit messenger RNA (the intermediary between the chromosome and machinery of protein synthesis in the cell) from which unsplit DNA, suitable for inserting into yeast, can be made with increasing ease.

- Inasmuch as there is some redundancy in the genetic code, yeast tends to share with mammals certain preferences of codon usage that are not favoured by bacteria; consequently yeast may find it easier than bacteria to decode mammalian genes.

- Yeast appears to have much the same ability as mammals to add carbohydrate groups to newly synthesized proteins, something bacteria cannot do; the carbohydrate groups may be essential for the activity of certain proteins.

- From at least the time that Bacchus sprang from the thigh of Zeus, there has been an accumulation of knowledge of the large scale culture of yeast. By comparison, bacterial culturing is still in its infancy, which perhaps explains the continuing problem of "phage-out", the disaster that befalls a bacterial culture when it is attacked by a bacterial phage or virus.

Peter Newmark

Thatcher applauds genes

Britain's Prime Minister, Mrs Margaret Thatcher, was told last week that the public stood to gain an annual return of 157 per cent on its investment in basic research into the applications of recombinant DNA techniques through cost reductions in pharmaceutical and other commercial products. In comparison, the heavy investment in research and development, as well as production facilities, meant that companies might on average expect a more modest return of about 15 per cent.

Mrs Thatcher was given these figures by Dr Leslie Glick, president of the Rockville-based company Genex Corporation, when she visited the company's laboratories during her stay in Washington. Dr Glick said that the company had calculated that in 20 years time, \$40,000 million out of \$125,000 million in worldwide sales of a variety of products would be obtained by using genetically engineered microorganisms. Out of the total, \$140,000 million would be obtained from microorganisms making products that already exist, and the remaining \$26,000 from products which are not now economical to make.

These figures would translate into earnings of \$3,500 million for corporations after 20 years, half coming from petrochemicals being made biologically. Total private investment in plant, equipment and research and development would total \$24,000 million; in contrast, public support for basic research was likely to be at the most \$3,000 million, whereas the public would benefit by \$2,400 million in savings and \$2,300 million in taxes on products sold.

Mrs Thatcher said that she "totally agreed" with Dr Glick's reservations about attempting to promote genetic engineering technology through government investment rather than private entrepreneurship. Individual investors were willing to risk something if they stood to gain a great deal, she said, and it was also exciting — "better than betting on horses".

Darwin in California

No verdict

Washington

Biology teachers in the United States are breathing a little more easily this week. Last Friday, a California judge ruled that the teaching of evolution in schools does not necessarily undermine the religious beliefs of those who accept the biblical description of human origins. The claim has been made by Mr Kelly Segraves, director of the Creation Science Research Center in San Diego, in a suit brought against the state's Board of Education on behalf of his son. But, after broad philosophical questions about conflict

between the Darwinian and "creationist" interpretations of biology had been reduced to the narrower question of whether evolution is being taught too dogmatically in Californian schools, the judge ruled that he found little wrong with the state's present practices.

The case had excited wide interest and had been widely talked about as a successor to the Scopes "monkey trial" in Tennessee in 1925. Last week, the creationists swept in like lions, charging that the teaching of Darwinian evolution in schools was an offence to their religious beliefs, and thus a direct infringement of the First Amendment, which guarantees freedom of religion, but they left relatively tamed, arguing merely for changes in the guidelines which the state provides for public school biology teachers on how evolution should be taught. Their demands that alternative theories about human origins should be discussed in biology classes were dropped.

The turning point came on the second day of the trial, after the plaintiffs' attorney had claimed that there was a direct conflict between his clients' beliefs and the state's approach to teaching evolution, exemplified by the current guidelines, which state that evolution "has been going on for so long that it has produced all the groups and kinds of plants and animals now living" as evidence that his clients' religious rights were being infringed.

The attorney, Mr Robert Turner, then surprised the court by withdrawing the original complaint that the state was trying to establish the teaching of a secular religion through school biology teaching. Judge Irving H. Perluss accordingly ruled out debate on the scientific beliefs of Mr Segraves and therefore any attempt to demonstrate the relative merits of creation theories and Darwinism. As a consequence, the defendants were not able, as they had planned, to call the twenty scientists recruited as witnesses for Darwinism by the National Association of Biology Teachers. They included Nobel Laureate Arthur Kornberg and astronomer Carl Sagan.

Another issue ruled out by the judge concerned school teaching practices. On the second day, the plaintiff's son, 13-year-old Kasy Segraves, said he had been taught that man evolved from the apes "as fact". The defendants sought to call his teacher as a witness, both to repeat a denial she had made in the press and to point out that the discussion had taken place in a social science, not a biology class. Judge Perluss refused to allow this line of argument, invoking a state law which bans evidence that would prejudice a case to a greater degree than the value of the evidence.

On the final day of the trial, a member of the state's Board of Education, Mrs Marian Drinker, testified that for the past eight years — and following earlier criticism of approved school textbooks by fundamentalist religious groups — the

state had adopted a policy that Darwinian evolution should be taught as theory and not dogma. The board had at the time issued a statement requiring that in school texts "dogmatism should be changed to conditional statements where speculation is offered for origins", and that they "should emphasize 'how' and not the ultimate cause for origins". In his judgement, the judge directed that the Department of Education should recirculate a memorandum containing this policy statement to all schools in California, to textbook publishers and to anybody else who had received the guidelines in the past or would in the future.

Even this was interpreted as a partial victory by the creationists, who argued that it represented "the first move in a chess game", and vowed to continue their fight against the teaching of evolution in schools. The state authorities and their scientific advisers, however, said that the verdict was a complete vindication of the way that evolutionary theory is at present taught in biology classes, pointing out that the judge in his summing up had stressed the importance of not mixing religion and science.

David Dickson

European space agency

Sixes and sevens

The plans of Eric Quistgaard, the new director-general of the European Space Agency (ESA), have thrown the 11 member states into hot dispute over the agency's future. Three months after the plans were announced, the delegates to the council are no nearer agreeing a draft that would lay down the agency's structure and aims for the next 10 years. The fear that ESA may collapse if member states cannot reconcile their individual ambitions may be realized if agreement is not reached within a few months.

ESA suffers from all the troubles of multi-national, multi-purpose agencies. The latest crisis has been brewing for the past two years as the agency's two largest projects, the Ariane launcher and Spacelab, have been drawing to a close and no new projects of comparable size have been agreed to replace them. Quistgaard's solution, to reduce the agency's total budget from about £480 million to £285 million a year by 1982, has been agreed by most member states. But his suggestions as to how the reduced budget should be spent have opened up old wounds.

West Germany is the only country so far to support Quistgaard's plan to increase the mandatory science budget by 50 per cent over the next decade. Although all are thought to support the notion that the European scientific community should support more space science, few are willing to commit the funds which they would prefer to spend as they wish on voluntary programmes.

The reduced budget will mean that some

selectivity is necessary and the latest dispute seems to be over which programmes the agency should concentrate on. The principal candidates are telecommunications, space transportation systems and Earth resources, with Spacelab and rocket-borne micro-gravity experiments a minor option.

The option standing the greatest chance of success is the Earth resources project. Many member states agree that Europe should be more active in the field, and a decision is due later this year on whether to go ahead with ERS 1, ESA's first remote sensing satellite for oceanographic studies. A more controversial plan for future Earth resources satellites is also to be planned.

But the greatest dispute is over what should be done about telecommunications, supported by Britain, Italy and the smaller countries, and space transportation systems, supported by France. France and Germany, by far the biggest space spenders inside and outside the agency, opted out of ESA's Large Communications Satellite (L-sat) when they decided to build jointly a large satellite for direct broadcasting. Both countries would prefer telecommunications satellites, already showing commercial potential, to be built outside ESA which is primarily a research and development agency.

The future of L-sat will probably be assured later in the year when Britain, Italy and the smaller nations give it their approval. The question then will be whether to build the next generation of advanced telecommunications satellites within the agency or within French and German industry. The issue is particularly sensitive for Britain, which has recently

decided to build up its telecommunications industry in the hope that ESA could provide more support.

The dispute has driven the ESA members into two camps — the smaller countries led by Britain, and France and Germany who put up most of the money for Ariane and Spacelab. It is feared that France and Germany could decide to contribute even less to the agency than M. Quistgaard's plan envisages, preferring instead to put more money into their own well-developed space industries. That could weaken the agency to the point where it could not afford to run its own basic support facilities. As yet, however, according to one official, nothing is certain and anything is possible. The next few months should determine the future.

Judy Redfearn

Chemical warfare

Budget increase

Washington

The first signs that President Reagan will implement his election promise to produce chemical weapons came last week in the Defense Department's budget proposals. The Pentagon has confirmed that the \$222,200 million budget for the next fiscal year will include \$20 million for construction work on a plant at the Pine Bluffs arsenal in Arkansas for producing binary chemical weapons.

Provisional approval for the building of the plant was given by Congress last year, but since then there has been intense lobbying by church groups and other protesters, while the previous Defense Secretary, Harold Brown, was lukewarm on the project. This is why funds for the first stage of its construction were not included in President Carter's budget submitted to Congress early in January.

Pentagon officials are at pains to emphasize that the request for \$20 million does not necessarily mean that Mr Reagan plans to end the moratorium on the production of chemical weapons begun by President Nixon in 1970. But they think that the new president is "leaning in that direction" and that his second budget a year from now would ask for a further \$140 million to build full-scale manufacturing facilities.

Throughout the past decade, the US Army has kept up the pressure for reduced production, arguing that even if only a small stockpile of chemical weapons were required for deterrence, binary weapons could be stored more safely than those in which active chemical agents are present from the start. For some time, the army has been embarrassed by the leakage of nerve gas from "Weteye" bombs stored in Colorado.

Congress refused to fund the construction of binary weapons in 1975 and 1976, with the result that the US Army's interest in going ahead was dis-

couraged by the White House in succeeding years. There is, however, evidence that President Carter may have relaxed his previous opposition to chemical weapons shortly before leaving office. The Arms Control and Disarmament Agency said, when the president's last budget was published in January, that the Administration had agreed to an increase of chemical weapons activity within the Defense Department. The agency estimated that expenditure would grow from \$2 million in the fiscal year 1981 to \$14.4 million in 1982.

Among the projects foreseen in the Carter budget were the experimental development of new binary weapons (\$2.2 million) and the development of a binary spray bomb in which all three services had an interest. Production of this weapon, called "Bigeye", will require both presidential and congressional approval, as will the production of the 8-inch and 155-mm artillery projectiles now under development. One of the issues that will concern both the White House and Congress is the effect of a decision to resume production on the negotiations with the Soviet Union on a chemical disarmament treaty, which has been discussed in Geneva since August 1976.

The Defense Department also asked Congress in January for \$44 million for "chemical defense science and technology" projects in 1982. This is considerably higher than in previous years, and follows recommendations about necessary improvements to protective equipment, warning devices and medical treatment made last summer in a study conducted by the Defense Science Board.

David Dickson

One step to LEP

The UK Advisory Board for the Research Councils has recommended to Secretary of State Mark Carlisle that Britain should support LEP — the SF 960 million electron-positron collider planned for the European subnuclear physics laboratory, CERN, near Geneva. If Mr Carlisle accepts the board's advice, British delegates at CERN's June council meeting will vote for LEP to be included as an integral part of CERN's future programme, not as a separate project as some factions — particularly in Sweden — would like.

Meanwhile, LEP has shrunk — if not in cost, in size. A new design has LEP only 27 km in circumference, so only 8 km of the accelerator tunnel will be under the French Jura Mountains to the north of the CERN site. In this way LEP will avoid a region of fractured and unstable rock — the "trias" — which was threatening substantial increases in civil engineering costs. Improvements in machine design will enable the new LEP to reach the same energy without any increase in power consumption.

Robert Walgate

Allen's successor

Professor John Kingman is to be the next chairman of the Science Research Council. He will take over from Sir Geoffrey Allen, who is returning to his old research group at Imperial College, on 1 October.

Professor Kingman, who will be leaving his niche as professor of mathematics at the University of Oxford, is an unusual choice, having had no experience of experimental science. His work has been in mathematics and statistics. Since 1979, however, he has been chairman of the council's science board. The board's zeal for awarding research grants was largely responsible for overspending by the council to the tune of £10 million in 1979–80.

The Department of Education and Science, which made the appointment, had apparently hoped to boost the council's image as a supporter of biological sciences by appointing a biologist, but no willing candidates could be found.

Judy Redfearn

Chemical industry

ICI off course

Britain's largest chemical company — Imperial Chemical Industries Limited (ICI) — is turning to biology to seek a long-term solution to its present financial difficulties. Speaking after the company's announcement of its worst share dividend since 1938, ICI's research director, Charles Reece, said that research priorities would now be in biology-related disciplines — coupled with efforts in composite materials and the by-product chemistry of new transport fuels.

A third of ICI's £200 million annual research and development budget is already linked to biology. Most of this goes into pharmaceuticals, forming the largest single component (18 per cent) of ICI's research. ICI also has the world's largest single-cell protein fermenter and has used genetic engineering to modify the protein-producing organism *Methylophilus methylotrophus* to improve its carbon efficiency (see *Nature* 287, 396; 1980). The modified organism is not in production yet, but only "technicalities" delay its use.

Reece would not say what products ICI would make through genetic engineering except "the obvious ones": proteins for human, animal and plant health. The company is paying special attention to plants — too little is yet known of plant molecular genetics to expect a quick return, but since it is an area of ignorance, it is also likely to be an area of opportunity.

But this is long-term thinking. In the short run, ICI is not about to jump on the bandwagon of small-volume, higher added value products recommended by the pundits of the chemical industry — unlike, say, BP Chemicals, which last week announced a £4 million investment in a new plant at Hythe to produce hydroxyalkyl-acrylates for speciality paints and other uses. Speciality chemicals, the argument goes, are — paradoxically — bought by many small consumers, whereas bulk chemicals are bought only by one or two large buyers. So if the bulk buyers go down, so does the supplier.

Pruteen — no food for the birds

ICI is not impressed by this generalist argument. The company is more concerned to estimate the precise needs of existing customers, who in a recession are being more exacting in the use of their money. This means that research and development in ICI should be related to those needs, but the difficulty is to distinguish long-term structural changes in needs from the effects of the recession, says Reece. One structural change might be the price of steel, with its high energy intensity; this is forcing consideration of substitute materials, particularly composites (rather than new polymers).

Another structural change would be the high cost of oil causing shifts to new fuels — such as syncrude from coal — which will have new chemistries and new spin-off feedstocks for the chemical industry.

So research effort should be concentrated on "C-1 and C-2" chemistry, the chemistry of molecules with low numbers of carbon atoms as potential feedstocks. This would also provide flexibility: whatever the principal transportation fuel source turns out to be, its products could be cracked down to low-carbon molecules to begin higher synthesis.

Back in the factory, production processes could be optimized to the new economics — emphasizing thermodynamic balance for energy or feedstock efficiency, for example, or reducing the capital cost of equipment to allow product flexibility.

Tight environmental regulations are strangling new products, Reece believes. "Try to get water through regulation now — you'd fail." There is an element of double standards for new and existing products. But the regulations, seen in another light, can provide competitive research opportunities: to improve the selectivity of a pesticide, for example, so it might pass regulation more quickly.

But, overall, research in ICI is being seen as just another part of the business, which must tighten its belt and show its economic effectiveness like all other divisions. The days when ICI's corporate laboratory in Runcorn, Cheshire, was called "ICI's university" are over.

Indian oil exploration

Partners sought

Lucknow

Faced with the urgent need to find more oil, and the accompanying huge capital risk, the Indian government has decided to invite foreign oil companies to conduct oil exploration. A short list of 34 companies has been drawn up and contracts will be let on a production-sharing basis only to companies agreeing to sell their share of crude to India at a fair market price.

The government is offering exploration rights on 32 blocks — 15 onshore and 17 offshore — a total of about 0.66 million km². The public sector Oil and Natural Gas Commission will represent the government as a "non-operating" party in all exploration contracts and will be given full decision-making rights on any discovery.

At present, oil exploration is carried out by the commission and Oil India Limited. The commission has discovered 585 million tonnes of recoverable oil and gas reserves, whereas Oil India has found only 47 million tonnes. According to a report jointly prepared by Soviet and commission experts, however, there are reserves of 12,700 million tonnes of oil, of which 8,700 million tonnes are in offshore and 4,000 million tonnes in onshore areas.

Commercial reserves were first discovered in the early 1920s in the Assam region, and in the mid-1970s crude was commercially produced in Assam and Gujarat states. Offshore exploration began in the early 1960s, and in the mid-1960s reconnaissance surveys by a Soviet seismic ship, Akademik Arkhangeliskey, delineated certain structures including the Bombay High. Oil was discovered there in 1974 and production began in 1976. By last year, 88 exploratory and assessment wells had been drilled, of which 31 had proved to be dry. Other commercial discoveries include the offshore structures Ratnagiri, North Bassein, South Bassein and Tapti.

The Indian Planning Commission has allocated 30,000 million rupees (£1 = R17.90) for oil exploration during the sixth plan period 1980–85, which includes R18,370 million for offshore activity. So far, offshore exploration has cost R7,250 million with total discoveries of 250 million tonnes of oil and 270,000 million m³ of gas — a potential value of R50,000 million in crude alone.

India spends a sizeable amount of foreign exchange earnings on oil imports. During 1981, indigenous production will be 14–15 million tonnes, less than half domestic demand of 31 million tonnes, so R60,000 million will be needed to fill the gap. By 1985, the demand is expected to reach about 47 million tonnes, with indigenous production reaching only 21 million tonnes.

The Bombay High development is being financed by the World Bank, which recently offered a second instalment of

\$400 million, having provided \$150 million in 1977. During their recent conference in Vienna, OPEC finance ministers also approved an interest-free loan of \$30 million for the project. The present plan is that production capacity will rise to 12 million tonnes per annum.

The collaboration now sought with foreign companies is not new to India. In the 1970s, for example, the government invited two American and one Canadian group of companies to explore. They left, however, after finding their wells dry. India has also been collaborating with other countries in contract surveys and recovery or increased production technologies.

Zaka Imam

UK pharmaceuticals

Bad risks

The problems of getting new drugs onto the market have been brought home to two British pharmaceutical companies in the past few weeks. Fisons, after many years of costly development, have had to abandon the antiasthmatic drug Proxicromil in the face of evidence of ulcerogenic and carcinogenic activity in rats. And Beecham's new antibiotic combination, Augmentin, has received a cool reception from the government's Committee on the Safety of Medicines.

In Proxicromil, Fisons thought they had found a successor to their major money-maker Intal (cromolyn). During the past 10 years, Intal has proved to be one of the most effective inhaled antiasthma drugs. But Fisons' patent on Intal lapses in 1982, and other manufacturers will be able to produce alternative forms of cromolyn.

Since 1973, the company has spent between £12 and £15 million on developing Proxicromil as an orally administered alternative. Clinical trials had been very encouraging, and it looked as if Fisons had succeeded where others had failed and had found a drug which could be taken in the high doses needed by the oral route without having unacceptable effects away from the site of action.

But late in the day, only last October, long-term animal toxicity tests began to show that Proxicromil induced ulcers and renal tumour. Fisons acted quickly and halted further work on the drug despite the massive investment already made. Proxicromil had been expected to bring the company earnings of about £10 million a year, and the immediate reaction on the stock market was to reduce the market value of the company's shares by £10 million.

Trouble in the drugs division comes at an awkward time for Fisons. Four fertilizer plants are to be closed, while the company is also suffering from the general slump in the heavy chemicals industry. Last year, Fisons made a net loss of £16.8 million compared with net profits of £12.1 million the year before. Other cost-cutting moves

include closure of the London office.

Beecham's immediate problems are not so grave. But the Committee on the Safety of Medicines, which is technically advisory to the Department of Health, is quibbling with the company over the indications which should be listed for its new antibiotic Augmentin.

This is a combination of the semi-synthetic penicillin amoxicillin with clavulanic acid. The clavulanic acid is there to block the action of β -lactamase enzymes produced by penicillin-resistant organisms and so protect the active amoxicillin.

The committee is broadly suspicious of any combination of drugs, considering that general use might cause problems of multiple drug resistance in the long term. It seeks to restrict the use of Augmentin to only the severest of infections in adults and has suggested it be used only for infections with Gram-negative bacteria, mostly urinary tract infections and bacterial gastroenteritis. Beecham had in mind a wider range of applications. What happens now is that the company will resubmit its views to the committee, pointing out the benefits to be had by a wide use of Augmentin. And sooner or later a final list of indications will emerge.

Charles Wenz

Telecommunications

Bell's bother

Washington

The future of one of the world's largest private research institutions, the Bell Laboratories, once again hangs in the balance following the failure of its parent body, the American Telephone and Telegraph Company (AT&T), to reach a settlement with the US Justice Department on anti-trust charges.

The trial of the Justice Department's suit against AT&T opened on Wednesday, 4 March in New York. The lawyers are settling in for what may be a two-year spell. Last month, a day after the suit had come to court, the case was adjourned when both sides informed Judge Harold H. Greene that the "framework" for a consent decree settlement had been reached. The trial was deferred to allow the details of the settlement to be worked out providing the ground rules under which the company will be allowed to operate in new areas of telecommunications, such as information processing. A fortnight ago, however, negotiations over the terms of the settlement broke down.

The suit filed by the government alleges that AT&T had abused its monopolistic power over the US telephone system in the 1960s and 1970s, and required the company to divest itself of various parts. This would have included not only 23 operating telephone companies and an equipment manufacturer, but also part of the Bell Labs, where much of the world's basic research into telecommunications is

carried out. Although no formal announcement was made by either side about the rumoured settlement, it was generally believed that the laboratories would not have been affected.

With the breakdown of the negotiations, however, there is no longer any assurance that the laboratories will remain untouched, and it seems likely that the final settlement could be less favourable to the company.

A major uncertainty at present is the likely attitude of the new Administration, whose refusal to approve the framework negotiated under the Carter Administration has been cited as one of the reasons for the delay in reaching an agreement.

Last week, President Reagan announced the nomination of Stanford law professor William F. Baxter as Assistant Attorney General in the Department of Justice responsible for anti-trust affairs. Mr Baxter has previously spoken out against large divestiture cases, and the Office of Management and Budget has recently proposed terminating the anti-trust activities of the Federal Trade Commission, both factors which were thought to be in AT&T's favour.

However, lobbyists for AT&T's competitors cite a paper in the American Bar Association's *Antitrust Journal* written by Mr Baxter in 1977 in which he argues that divestiture may be the appropriate remedy in cases involving regulated monopolies.

The resumption of the trial has also provided an excuse for renewed attempts on Capitol Hill to develop legislation aimed at breaking up AT&T, on the grounds that the future control of telecommunications technology is too important to be left to regulatory commissions or to the courts.

Last week, Timothy Wirth, the new chairman of the House subcommittee on telecommunications, consumer protection and finance, said that the House was prepared to step in with legislation to increase competition in the telecommunications industry. Members of the Senate Commerce Committee are also considering draft legislation.

Last year, the House committee passed legislation which would have required the company merely to undergo an internal restructuring, setting up a subsidiary to carry out the research and development of competitive services. Such legislation had long been sought by AT&T, but was opposed by its competitors on the grounds that it would be pre-empting the Justice Department suit.

The latest challenge to AT&T comes from a group of shareholders, who are proposing at the company's annual meeting next month that it change its name to either American Telephone and Technology Inc. or American Telephone and Telecommunications Inc. to reflect the new areas of operation that the company is keen to enter. Both changes are opposed by the company itself.

CORRESPONDENCE

New IQ test?

SIR — Mackintosh¹ finds my theory of intelligence “distinctly simple” but allows that the findings of the inspection-time (IT) studies are “possibly very important”. I largely agree with him on both counts. No one who has steeped himself in modern “cognitive psychology” — with its legions of black boxes, “executive programmes” and “subroutines”, resembling phrenology in all but the apparent infinity of the number of mental mechanisms that are now conjectured — can readily accept that intelligence is truly general or unitary. As Mackintosh writes, “there might be a variety of independent traits, which happened to correlate with one another in the general population.” Such a lofty invocation of chance “happenings” is commonly preferred by cognitivists to any systematic endeavour to explain why so many measures of mental ability correlate positively as they do.

Professor Mackintosh writes: “A correlation between IQ and inspection time does not mean that IQ is mental speed, nor even that speed is one (of several) causes of IQ.” I quite agree with him on the first point — if only for the reason that it is important to distinguish between the hypothesized “mental speed” on the one hand and its natural, developmental products (in conventional IQ) on the other. But Mackintosh offers no support for his suggestion that the causal relationship between speed and IQ “might even go in the reverse direction”. It is easy, and indeed very traditional to suggest that a higher IQ gives a person many advantages. But why should one of the largest of these advantages — larger than those for educational attainment, income or social prestige — be in judging briefly presented line-lengths? Again, if IQ were causal to IT, it should be noted that one of the studies which I have reported (by Brenda Hosie) found a strong correlation (−0.78) between IQ and IT in children who were only four years old. This hardly looks like a straightforward case of a high IQ providing numerous, small and cumulative advantages over a long period of development.

I do not claim to have “proved” that mental speed is psychologically and ontogenetically basic to IQ-differences. Indeed, even when it becomes possible to manipulate inspection times experimentally (by drugs, for example), mental speed differences may not be able to account for at least that 20 per cent of natural IQ variance that is widely agreed to be “environmental” in origin. However, I do suppose that scholars of cognitivist and environmentalist persuasions will need great imaginativeness to formulate explanations of the IQ–IT relationship that do not involve the concept of a unitary, underlying trait for which *g* is the time-honoured name and psychometric indicator, and for which “mental speed” will prove a convenient psychological short-hand.

There are numerous potential applications of the finding that IT (and, as Jensen and the Hendricksons find, “choice reaction time” and the “average evoked cortical potential”) can apparently serve to index intelligence. It should at last be possible to operationalize the

concept of intelligence in studies of young human infants and of other species; and this may lead to rapid advances and changes in the understanding of how intelligence is controlled and of how it develops. But Mackintosh doubts that any results obtained with different human racial groups could influence cherished convictions. I fail to understand why. My own view — outlined in a forthcoming paper — happens to be that conventional measures of fluid intelligence are not quite such pure measures of *g* as Jensen loyally maintains: this is principally because some of them are a little contaminated by *k:m* (or “spatial abilities”). I, for one, would feel obliged to modify this view if IT indices gave Afro-Americans the same degree of disadvantage that they have on conventional measures of IQ. Whether “the critics of IQ” could ever be persuaded to change their views as a result of such studies is not the question. So long as the IQ–IT relationship proves generally replicable, new evidence about IT in non-WASP subjects should have appropriate effects on the scientific views of all reasonable people.

Darwin's survival

SIR — Your leading article “Darwin's death in South Kensington” (*Nature* 26 February, p.735) illustrates “the rot at the museum” by quoting a passage from our 1978 *Guide*. How odd, for that passage was drafted (by me) as a conscious paraphrase of the part of Chapter 13 in *The Origin of Species* in which Darwin discussed the relation between his theory and systematics. “Groups-within-groups classification”, which you take to be a “popular euphemism for cladism” and its attendant heresies, is not hidden propaganda but a contraction of Darwin's words — “the grand fact in natural history of the subordination of group under group.”

The “weasel words” which so incense you are “If the theory of evolution is true.” I have tried replacing them by your own criterion of truth: “If the theory of evolution is not an open question among serious biologists, the features used to classify species in groups . . . were acquired by the common ancestor of the group.” It does not read well.

Your readers may try the substitution in the equivalent passage from Darwin: “on the view that the natural system is founded on descent with modification . . . the characters which naturalists consider as showing true affinity between any two or more species, are those which have been inherited from a common parent.” And your readers can answer for themselves your question “what purpose except general confusion can be served by these weasel words?” The reader may also be able to judge whether the rot is to be found here or in Little Essex Street.

COLIN PATTERSON

British Museum (Natural History),
London SW7, UK

SIR — As working biologists at the British Museum (Natural History) we were astonished to read your editorial “Darwin's death in South Kensington” (*Nature* 26 February, p.735). How is it that a journal such as yours that is devoted to science and its practice can advocate that theory be presented as fact? This is the stuff of prejudice, not science, and as scientists our basic concern is to keep an open mind on the unknowable. Surely it should not be otherwise?

You suggest that most of us would rather lose our right hands than begin a sentence with the phrase “If the theory of evolution is true . . .” Are we to take it that evolution is a fact, proven to the limits of scientific rigour? If that is the inference then we must disagree most strongly. We have no absolute proof of the theory of evolution. What we do have is overwhelming circumstantial evidence in favour of it and as yet no better alternative. But the theory of evolution would be abandoned tomorrow if a better theory appeared.

Charles Darwin died nearly a century ago and is honoured at South Kensington as a great man of science. It does neither him nor science any service to misrepresent the status of his work.

Conservation sites

SIR — It can hardly be doubted that the number of species alive today is much smaller than the number of extinct species, nor that the future, unless it be preternaturally terminated, will see a proliferation of types of life exceeding all which have gone before. From this I conclude that extinction is the normal if not the necessary consummation of any species. If this is so, to attribute value to any species simply because it happens to co-exist with an observer, and still more, to attribute greater value to a species which, by its rarity, demonstrates its biological deficiency, reveals in that observer either or both a level of prejudice and lack of reason which gives cause to doubt his judgement on the matter of conservation even though he be a professional. Yet this is the essence of the action of the Nature Conservation Council in designating “sites of special scientific interest”. Were these sites to be set up with no loss of freedom to anyone, and more importantly, no cost to any individual, their institution might be treated as innocent caprice. The real consequence of the foolish advice given by the Nature Conservation Council is that their political masters impoverish the owners of the land involved, in the belief that they are preserving a national or even international treasure. Dr Goode of the

NEWS AND VIEWS

The intergalactic medium

from Joseph Silk

To many astronomers, the search for intergalactic matter resembles the quest for the holy grail. Theory tells us unhesitatingly that the remnants of the huge clouds out of which galaxies formed should still be in intergalactic space. The process of galaxy formation, like practically everything else in astronomy, was inefficient. The vestiges of protogalaxies, or embryonic galaxies, should pervade the Universe as wispy filaments or clouds, and be embedded in a uniform intergalactic medium (IGM) from which every structure we observe today must once have condensed. Theory tells us, and here it develops philosophical undertones, that the Universe was once very simple. A homogeneous and isotropically expanding substrate is the stuff out of which our cosmological models are made, as are the galaxies. Small fluctuations and slight deviations from perfect uniformity were amplified by the inexorable process of gravitational instability, eventually growing into protogalactic gas clouds that collapsed and fragmented into vast systems of stars.

How much matter is left behind is an open question. It is very likely that only a small fraction of the matter in the Universe has formed the visible regions of galaxies. Observations of galaxy rotation and the dynamics of galaxy groups and clusters have indicated the existence of a considerable amount of dark matter. Unseen by any astronomer, this matter nevertheless dominates the gravitational potential in the haloes of galaxies and in bound systems of galaxies. It is a component of the Universe, perhaps the dominant component, that has failed to collapse and make stars in the same manner as the inner regions of galaxies. The dark matter does not consist of gas, otherwise it would be visible. But what it is, we cannot tell. Speculations abound, the current favourite being massive neutrinos.

The luminous regions of galaxies consist overwhelmingly of stars, and these have formed from clouds of gas. We see this process of star formation continuing today in interstellar molecular clouds. The Milky

Way galaxy is a mature system, most of its stars having formed long ago from a much larger gas cloud. The remnants of clouds like this, and the gaseous medium out of which the cloud itself condensed, constitute the elusive IGM.

The search for traces of the IGM has been long and often fruitless. Reputations have been made and broken, often only for what has finally proved to be a new, perhaps stronger, upper limit on what might or might not be present in intergalactic space. Radio, optical, space ultraviolet, X-ray and γ -ray astronomers have all confronted the challenge, and all have failed to find the elusive, uniform IGM.

One early attempt utilized the 21-cm absorption line of atomic hydrogen to search for neutral intergalactic gas along the line of sight to the radio galaxy Cygnus A. No feature was found, and an upper limit was set.

The most stringent limit on the presence of a neutral intergalactic medium came with the discovery of quasars. Sufficiently distant that the cosmological redshift brought the Lyman α line of hydrogen into the visible part of the spectrum, quasar spectra were searched for a possible absorption 'trough' due to intergalactic neutral hydrogen. Failure to detect such a feature meant that, in the region of the Universe that was probed, less than one part in a million of an IGM of density sufficient to close the Universe can exist in neutral form. Subsequent space observations have extended the search for a Lyman α absorption trough into the ultraviolet region of the spectrum in the nearby quasar 3C 273, and confirmed that the IGM, if it exists, must be highly ionized and hotter than 10^6 K.

Such a hot IGM would lead to copious X-ray emission and the discovery in the earliest days of X-ray astronomy of a diffuse background of X-ray emission

produced some evidence for it. However, recent satellite observations with the Einstein observatory have revealed that quasars can account for a substantial fraction (over 50 per cent) of the X-ray background. At the same time, evidence for hot intergalactic matter has been found in X-ray studies of galaxy clusters. These contain substantial amounts of X-ray-emitting gas that is enriched to near the level of the Sun with certain heavy elements. High-resolution observations of quasar spectra have also revealed the presence of discrete intervening clouds of intergalactic gas. But despite the accumulating evidence for intergalactic matter in localized regions, the hypothesized uniform IGM that is so cherished by cosmologists has still not been found.

A recent paper by Paul Shapiro and John Bahcall (*Astrophys. J.* **241**, 1; 1980) makes an especially intriguing proposal which will extend the search for a Lyman α absorption (which led to a severe limit on a neutral IGM) to the remaining possibility of an ionized IGM. The authors suggest that detection of a hot, ionized IGM may be possible through observations of the X-ray absorption spectra of quasars. Extending earlier calculations by Richard Sherman (*Astrophys. J.* **232**, 1; 1979) they note that quasars, as a class, are sufficiently luminous X-ray sources to be observable at a redshift greater than 2 or 3. If sufficient atoms heavier than hydrogen are present in a hot IGM they will produce absorption troughs in the X-ray region of the spectrum, due to excitation of inner electrons around the heavy atomic nucleus; iron, for example, has a characteristic absorption at a few keV. Broad absorption troughs in the X-ray spectra of distant quasars would therefore be strong evidence for a hot, ionized IGM with a density amounting to a substantial fraction of the closure density and containing a near solar abundance of heavy atoms. Future space experiments with X-ray detectors capable of moderate energy resolution and high sensitivity should be able to perform this measurement within the next decade. □

Joseph Silk is a professor at the Department of Astronomy, University of California at Berkeley.

Directing toxins to cancer cells

from Sjur Olsnes

A CENTRAL PROBLEM in cancer chemotherapy is the lack of selectivity of present anti-cancer drugs. One attempt to improve this selectivity has involved the linking of cytostatic drugs, like daunomycin, adriamycin and methotrexate, to antibodies against tumour-associated surface antigens^{1,2}. The ability of such complexes to kill malignant cells selectively has, so far, been limited. Blythman and his colleagues (see this issue of *Nature*, p.145) are among those who have tried an alternative approach, whereby a toxin, instead of a drug, is linked to the antibody, and have now succeeded in producing a complex which is not only toxic but also highly selective.

The limited success of the drug-antibody complexes may be partly due to the fact that the cytostatic drugs act stoichiometrically and a large number of molecules is required to kill a cell. Even if the antibodies have the required selectivity (and it is not yet clear to what extent the corresponding antigens are tumour specific), they are usually obtained in such low amounts that the number of complexes reaching the tumour cells and binding to them may be very small. Furthermore, if the cytostatic drugs are for some reason released from the antibody, their non-selectivity is restored.

Interest in the preparation of tumour-specific cytostatics has recently increased for two reasons. First, the hybridoma technique permits the production of large amounts of monoclonal antibodies to a variety of cell-surface antigens, including tumour-associated ones. Second, the extreme toxicity of certain bacterial and plant toxins — a single molecule may kill a cell — might compensate for the small amount of complexes accumulating in the tumour.

Diphtheria toxin, abrin, ricin and related toxins all consist of two polypeptides with different functions. A binding polypeptide (B), with specificity for receptors at the cell surface, is linked by a disulphide bond to an enzymatically active polypeptide (A), which enters the cytoplasm and inactivates components of the protein-synthesizing machinery. Clearly, if the B-polypeptide is replaced by an antibody to a tumour-associated antigen, the enzymatically active A-polypeptide might be selectively delivered to the malignant cells. It is also important that the A-polypeptide alone is not cytotoxic.

In the first attempts to link diphtheria toxin to antibodies^{3,4} only marginal selectivity was achieved, but later studies have been much more successful. Thorpe *et al.*^{5,6} linked diphtheria toxin to anti-lymphocyte globulin and to F(ab')₂

fragments derived from it. These complexes were highly toxic to cultured human lymphoblastoid cells which are rather insensitive to diphtheria toxin alone. A chimera of diphtheria toxin fragment A and Fab' fragments of IgG from antiserum against L 1210 cells also showed selective toxicity in cell culture⁷. An interesting toxic conjugate was formed of ricin A-chain and anti-idiotypic antibodies against surface immunoglobulins on a B-cell lymphoma⁸. This procedure may have a more general application as idiotype antigens on the surface of B-cell lymphomas are, in fact, specific for the particular tumour cells.

During the past year four groups have reported experiments linking toxin A-chains by a disulphide bond to monoclonal antibodies against cell-surface antigens. In one case the antibody was against a colorectal tumour-associated antigen⁹, whereas in the others they were against normal surface antigens like IgM and IgD on B lymphocytes⁸ and the differentiation antigen Thy-1.2 on thymocytes¹⁰. In each case the chimaeric toxins were selectively toxic to cultured cells carrying the corresponding antigen.

The chimera or 'immunotoxin' formed by Blythman *et al.*, between ricin A-chain and a monoclonal IgM antibody against the Thy-1.2 antigen, was almost as toxic as native ricin to murine lymphoma cells (WEHI-7) carrying the Thy-1.2 antigen. In contrast, cells lacking the Thy-1.2 antigen tolerated 2,000–6,000 times more immunotoxin although they were fully sensitive to native ricin. The authors also demonstrate that treatment with immunotoxin significantly increased the survival time of mice challenged with WEHI-7 lymphoma cells. Although promising, the protection *in vivo* was less than expected from the cell culture data. There may be several reasons for this discrepancy. As pointed out by the authors, the two test systems used are entirely different — *in vivo* a few surviving cells may grow up to tumours and kill the animal, whereas in the cell culture assay a few surviving cells would hardly be recognized. Furthermore, *in vivo* the access of immunotoxins to the lymphoma cells may be reduced, for example due to the removal of the chimaeras by reticuloendothelial cells¹¹. Clearly, pharmacokinetic studies will be required to design the optimal type of immunotoxin.

Binding moieties other than antibodies have also been exploited. Several groups have made cytotoxic chimaeras by linking toxin A-chains to concanavalin A^{12,13} and other lectins¹⁴, to asialofetuin¹⁵ which is taken up selectively by receptors on hepatocytes, and to monophosphopentamannose¹⁶ which is bound and internalized by receptors on fibroblasts.

Particularly interesting are chimaeras between toxin A-chains and hormones like insulin¹⁷, the β subunit of human chorionic gonadotropin¹⁸ and epidermal growth factor¹⁹. The fact that the hormones are able to direct the toxin A-chain to the cytoplasm and kill the cell may be used to select mutant cells lacking hormone receptors and mutants with defects in the route of internalization. Such mutants may elucidate the functional significance of receptor-mediated endocytosis of polypeptide hormones. Not all hormone receptors may be able to internalize chimaeric toxins, as shown by Chang *et al.*²⁰ who could not demonstrate any toxic effect of a conjugate of diphtheria toxin fragment A and human placental lactogen.

Future work may take advantage of the fact that many plants accumulate considerable amounts of A-chain-like proteins which, as such, are not toxic to cells as they lack a B-chain. One of these proteins, gelonin, which is particularly abundant, became cytotoxic after being linked by a disulphide bond to concanavalin A²¹.

A limitation to the therapeutic use of chimaeric toxins is that, as foreign proteins, they elicit the production of neutralizing antibodies. This can, however, be considerably retarded if the toxins are given together with immunosuppressive cytostatic drugs²². Furthermore, the present availability of a variety of immunologically unrelated A-chains may allow a switch to another chimera as soon as an immune response is detectable. □

The world's worst weeds

from Robert M. May

MUCH has been written about the crop losses caused by insect pests and pathogens (see, for example, *Nature* 267, 669; 1977). Relatively less attention, however, is usually given to the roughly equal losses caused by weeds, which diminish agricultural yields and degrade rangelands and pastures by competing for water, light and nutrients.

Some time ago, in a survey of the problems caused by weeds in developing countries, Holm (*Weed Sci.* 17, 113; 1969) drew up a list of the ten worst weeds in the world. This list was based on guesses about the global losses of major crops, using data from the FAO and from the unfortunately sparse research literature.

Purple nutsedge (*Cyperus rotundus* L.)

Bermuda grass (*Cynodon dactylon* L. Pers.)

Barnyard grass (*Echinochloa crusgalli* L. Beauv.)

Jungle rice (*Echinochloa colonum* L.)

Goosegrass (*Eleusine indica* L. Gaerth.)

Johnson grass (*Sorghum halepense* L. Pers.)

Guinea grass (*Panicum maximum* Jacq.)

Water hyacinth (*Eichhornia crassipes* Mart. Solms)

Cogon grass (*Imperata cylindrica* L. Beauv.)

Lantana (*Lantana camara* L.)

Of these, eight are grasses or sedges and five are perennial grasses.

These villains are typified by the water hyacinth, of which Holm writes: "I have seen it in some of the major rivers of the world and I think it is the most massive, the most terrible and frightening weed problem I have ever known". The figure shows its present world-wide distribution. In developing countries, it chokes waterways and denies riverine communities access to the needed protein from fish in conventional fishing grounds. In the Far East, floods cause great islands of the weed to come crashing through the fences placed in rivers for fish culture. In addition, the weed provides an excellent habitat for many insects that are vectors of diseases of humans and other animals. The water hyacinth was deliberately introduced into the US as an ornamental plant in 1884, as part of a horticultural exhibition. Within 13 years, it had so clogged many waterways as to interfere with navigation, and by 1956 losses in the southern states were estimated at around 45 million dollars per year. In 1976, 15 million dollars were spent on efforts to control water hyacinth in Florida and Louisiana (Cox *Utah Sci.* 38, 59; 1977).

The story of the water hyacinth in the US is typical. Many of the world's top ten,

along with other weeds, have been purposefully introduced into America for one or other reason that seemed sensible at the time. Today, Williams (*Weed Sci.* 28, 300; 1980) estimates that such deliberately introduced weeds cost the agricultural industry millions of dollars each year in reduced yields of crops and livestock, and millions more in control costs. In Williams' words: "Many of these undesirable plants infest crops, others clog navigable or recreational waterways. Still others reduce the productivity and value of grazing lands,

area where halogeton was indigenous. The plant proved salt and drought tolerant, and its spread was not hindered, as it showed promise for forage and firebreaks; the literature of the time knew nothing of its poisonous properties. During the years of depression and World War II, when few weed scientists existed in the US and little money was available for research, halogeton spread rapidly throughout the Intermountain Region. As Williams observes: "By the time sheep losses were traced to halogeton, the plant was beyond

Map showing the distribution of water hyacinth over the warm regions of the world.

or they are poisonous and present a threat to the health of humans and livestock".

Williams asks how best to prevent accidental introduction of weeds, and he gives a tentative sketch of a programme to this end.

For non-poisonous plants, identification of potential pest species should not be too difficult, even though the flora in question ranges from small aquatics to exotic trees. Williams notes that a candidate for introduction should be examined for its capacity to invade crop lands, grazing lands, forests and waterways, paying attention to its methods of dissemination and the longevity of its seeds or other reproductive parts. One should be alert for undesirable characteristics known to be associated with other members of the genus or family to which the species belongs.

For plants that are pests by virtue of being poisonous, the screening process is trickier. Such plants are likely to be considered innocuous in their indigenous setting, or they would not be candidates for introduction; but the plant may, in fact, be poisonous, or may become so under unfamiliar environmental circumstances.

Williams points to halogeton as a classic example of a poisonous weed, whose introduction has been very costly. The plant was accidentally introduced into the western US around 1935, with the first plants probably growing from seed spilled from a train carrying products from an

control, much less eradication. Within 25 years after its discovery, halogeton had engulfed between 4.0 and 4.5 million hectares of desert range in Utah, Nevada, Idaho, Montana and Wyoming, and had invaded Colorado, Oregon and California. Thousands of sheep were killed by halogeton, sometimes 500 to 1,700 in a single day. Even though the plant is widely recognized and largely avoided today, single losses of several hundred sheep are often reported". Today a weed physiologist would recognize that salt-tolerant members of the family Chenopodiaceae often synthesize toxic amounts of soluble oxalates. Analysis of the plant for this compound would be indicated, and the deadly potential of halogeton and its implications for the sheep industry would immediately be apparent.

Williams suggests a combination of several lines of research towards early identification of such poisonous weeds. First, seed inventories should be inspected; a plant may be known to be poisonous, or may be closely related to a known toxic plant. Second, suspected plants should be subjected to chemical analysis for alkaloids, nitrates, nitro compounds, saponins, soluble oxalates, cyanogenetic glycosides, furocoumarins or other exotic toxins indicated for a given plant. Such indications may come from the third line of defense, chemotaxonomy; many plant taxa are related chemically, as well as

Robert M. May is Class of 1877 Professor of Zoology at Princeton University.

© 1981 Macmillan Journals Ltd

morphologically. As mentioned above, such chemotaxonomic considerations would today raise a red flag against halogeton. Another example is the sicklepod milkvetch (*Astragalus falcatus* Lam.), which was introduced around 1920 and has been recommended for range plantings for over 25 years; recognition that many *Astragalus* species contain toxic concentrations of nitro compounds led to identification of sicklepod milkvetch as poisonous, and efforts are now being directed to its eradication. Fourth,

introduced plants that are suspected of being poisonous may be fed to experimental animals, as extracts, dried plants, or residues.

With current pressures to strip-mine for coal, there is much interest in finding plant species that will grow on mine spoils, reproducing rapidly and providing erosion control, and, if possible, grazing for livestock and food and cover for wildlife. The clear need for such plants to be non-poisonous gives special urgency to the programme outlined above. □

Geomagnetic field modelling using satellite data

from David R. Barraclough

ACCURATE DESCRIPTIONS of the Earth's magnetic field are useful for navigational purposes and form the basis for many scientific studies. Such descriptions usually take the form of mathematical models, most often in terms of an expansion in spherical harmonics, and magnetic charts can readily be produced from the models. A major difficulty in producing geomagnetic field models has always been the acquisition of an up-to-date and well distributed set of accurate observations. As a satellite in a polar orbit can survey the entire globe in a matter of days, it was an obvious step to use such a satellite to measure the geomagnetic field.

The most recent satellite survey of the geomagnetic field was performed by the NASA/US Geological Survey satellite Magsat between November 1979 and June 1980. Magsat differed from previous geomagnetic survey satellites in that it was able to measure not only the strength of the field but also its direction.

Since the geomagnetic field is derivable from a scalar potential which satisfies Laplace's equation, it was possible to use the earlier satellite observations of F to refine existing models of the field. Although such models fitted the input F data very well (with a r.m.s. residual of about 10 nT), there was evidence that they did not describe the vector geomagnetic field as accurately (Ben'kova *et al.* *Bull. int. Ass. Geomag. Aeron.* No. 152-163; 1971; Fabiano & Peddie *J. geophys. Res.* **76**, 3816; 1971). These findings led to several theoretical studies of the production of field models from F observations alone.

Hurwitz and Knapp (*J. geophys. Res.* **79**, 3009; 1974) and Barraclough and Nevitt (*Phys. Earth planet. Interiors* **13**, 123; 1976), using simulated data with noise added, verified that good fits to F did not

guarantee a good description of the other field components. In particular, large errors in the vertical component (Z) of the field occurred near the dip-equator (the line of zero inclination). In terms of the coefficients of the spherical harmonic model, those having equal values of m and n were least well determined. These are the sectorial harmonics, which divide the surface of a sphere into segments like those of an orange. It was also shown that the large errors could be removed by using small amounts of vector data (about 10 per cent of the total) covering the equatorial region.

Hurwitz and Knapp (*op. cit.*) and Lowes (*Geophys. J. R. astr. Soc.* **42**, 637; 1975) showed that the root of the problem lay with what they termed the perpendicular error effect. When fitting only a single component of a vector field, the perpendicular components synthesized from the resulting model can have errors associated with them which are considerably larger than the errors in the component fitted. This results from the lack of constraints in the perpendicular directions. In some cases, for example the production of models from Z data only, the perpendicular error effect is of minor importance because of the particular configuration of the geomagnetic field. It turns out, however, that fitting F data is a particularly bad choice. The perpendicular error effect leads to large errors in Z and these are especially troublesome where Z is small, that is, near the dip-equator, as noted above.

Backus (*Q. Jl Mech. appl. Math.* **21**, 195; 1968; *J. geophys. Res.* **75**, 6339; 1970; *Geophys. Res. Lett.* **1**, 21; 1974) investigated whether models derived from F data alone were unique and showed that, under certain conditions, they were not. In practical field modelling using real data these conditions for non-uniqueness are not fulfilled. Stern and Bredekamp (*J. geophys. Res.* **80**, 1776; 1975) have, however, shown that certain series of terms

in the spherical harmonic expansion, which Backus highlighted in his uniqueness studies, are likely to be relatively poorly determined in an analysis of F data alone. These series (which Stern and Bredekamp called 'Backus series') consist of terms which all have the same value of m . Each series starts with a sectional ($n = m$) term and succeeding terms have values of n equal to $m + 2, m + 4, m + 6$, and so on. In agreement with the findings noted above, Stern and Bredekamp found, using simulated data, that the terms with $m = n$ had the largest uncertainty for a given series.

Now that data are available from Magsat, it is possible to study these effects using real data. Stern *et al.* (*Geophys. Res. Lett.* **7**, 941; 1980), in one of the first reports of results from Magsat, have made an initial attempt at this. They have compared two models, one based on vector data from early in the Magsat mission (November 1979) and the other based only on scalar (F) data collected at about the same time. Values of Z computed from the two models differed by up to 2,300 nT at the Earth's surface and by up to 1,500 nT at the satellite's altitude. (For comparison, typical mid-latitude values of Z are of the order of 40,000 nT.) The differences, when plotted on a world map, showed a pattern of six foci, all positioned very near to the dip-equator. When the two models were compared coefficient by coefficient, those in the Backus series described above did indeed show larger differences than the coefficients not belonging to such series. There were suggestions that other effects were present affecting the 'non-Backus' terms and work is in progress in this area.

Thus, the doubts cast on geomagnetic field models based solely on F data seem to be confirmed. Fortunately there are relatively few such models and most of these have been produced for specific purposes related to the scalar data on which they were based. Most producers of models for navigational and general scientific purposes (for example, Barraclough *et al.* *Geophys. J. R. astr. Soc.* **43**, 645; 1975; Barker *et al.* *Geophys. J. R. astr. Soc.* in the press) have been careful to use F observations as only a part of the input data and their models will therefore be free from the deficiencies discussed above. Potential users of field models should be wary in their choice of models. Field models based solely on F data can be used with some confidence if one is interested only in the intensity of the geomagnetic field. If vector information is needed it is best to avoid such models and to use instead one of the models based on component data as well as F data. The International Association of Geomagnetism and Aeronomy, at its next scientific assembly this summer, plans to recommend an International Geomagnetic Reference Field which should provide a set of reliable models describing the geomagnetic field since 1965. □

Hydrothermal activity at mid-ocean ridge axes

from J.M. Edmond

THE existence of hydrothermal activity at oceanic spreading centres has long been suspected but it was only four years ago that the first direct observations¹ were made. During dives of the submersible *Alvin* in Spring 1977, fields of hot springs were discovered at a depth of 2,500 metres on the Galápagos spreading ridge (86°W). The hot spring water had an exit temperature 15°C above that of the surrounding ocean (~2°C) and had produced a thin coating of manganese oxide on the surrounding basalt pillows. Fields of hydrothermally produced mounds composed of nontronites (iron-rich clay minerals) and covered by a pure manganese dioxide crust were also found off-axis in sediments covering 300,000-year old crust².

Systematic work on the chemical composition of the hot springs showed them to be seawater that had reacted with hot basalt at a temperature of about 350°C and then mixed with waters from the ambient ocean³. It was concluded that the mixing had occurred sub-surface and that the observed temperatures in the throats of the vents, and their variations, depended on the extent of this process. Given the highly permeable crust close to the ridge axis it appeared unlikely that the 'neat' high-temperature end-member would ever be directly observed although it seemed likely to be an ore-transporting solution. Since the sulphide-forming elements are removed as the temperature and pH fall during mixing and cause the disseminated mineralization observed in dredged and drilled rocks, it is not possible to 'see through' the mixing zone to the ore metal chemistry of the primary solution⁴.

Most of the major ions — sea salts — are unaffected by this, however. It was therefore possible to estimate the effect of ridge crest hydrothermal activity on the bulk composition of seawater itself. The elemental fluxes are calculated as follows: the thermal budget has been estimated from the observed deficit in the conductive heat flow from young crust relative to that expected from simple plate models. The globally integrated value for the anomaly is approximately 5×10^{19} cal yr⁻¹. If all this heat is removed by hydrothermal convection at an operational temperature of 350°C, then a volume of water equivalent to the whole ocean must circulate through the ridge axis every eight million years. The flux of ³He required to maintain the saturation anomaly at mid-depth in the oceanic water column is roughly 6.5×10^{26} atoms yr⁻¹. The measured ratio of heat to ³He in the hot spring waters is 7.6×10^{-8} cal per atom⁵. If

it is assumed that all the ³He is supplied to the ocean by axial hydrothermal vents in the same ratio, the heat flux can be calculated. The value 4.9×10^{19} cal yr⁻¹ is in excellent agreement with the geophysical estimates. It seems plausible, therefore, to compute the fluxes for other elements in an analogous way. Although the circulation rate for water is only about 0.5% of that

input. Lithium, rubidium, calcium and barium are released in amounts comparable to or greater than those delivered from the continents. The manganese input from the axis is sufficient to account for the entire authigenic inventory of the element in deep sea sediments. The contemporary ocean is as volcanogenic as it is fluvial.

Exploration was next extended in areas of known hydrothermal activity in the hope that higher exit temperatures would be found. In 1978 the exciting news was received that the French CYAMEX team had discovered large deposits of iron-zinc-copper sulphides in the axial valley of the East Pacific Rise at 21°N, south of the mouth of the Gulf of California, with their manned diving saucer *Cyana*⁶. While no active hot springs were encountered, this was the first firm indication that something approaching the 'end-member' solutions could survive undiluted to the surface. The planned return to the original Galápagos site in spring of 1979 produced no dramatic developments. The subsequent *Alvin* dives at 21°N did. The French programme had been a reconnaissance survey for a collaborative geophysical programme. Two deep-towed instruments were involved: ANGUS, a sophisticated survey camera, and Deep Tow, a powerful array of geophysical sensors. Ocean-bottom seismometers were deployed in the axial valley, near-bottom gravity and magnetic measurements were made from *Alvin* and active ore-carrying hot springs were found⁷!

'Black smokers' — jets of mineral-laden waters — were observed debouching from constructional features several metres high. These 'chimneys' are formed of sulphides, sulphates, oxides and silicates precipitated as the hot spring waters mix with the ambient seawater. Subsequent dives in the area in the winter of 1979 found that the smokers actually exit as clear, homogeneous solutions with temperatures close to 350°C, as had been previously predicted from the Galápagos data. The major ion chemistry is very similar to that deduced from the low-temperature observations⁸. The end-member had been found. The 350°C waters are completely lacking in magnesium and sulphate, have an *in situ* pH of 4.7 and contain about 2 mmol l⁻¹ of iron and 0.1 mmol l⁻¹ of zinc. The black 'smoke' is composed of sulphides whose precipitation is induced by rapid mixing with the ambient water column. The ore-forming solutions for massive sulphide deposits, the subject of so much speculation, can now be studied directly.

In parallel with the exciting discoveries at Galápagos and 21°N there have been major developments on other fronts.

Picture taken by the research submersible *Alvin* at a depth of about 2,500 m on the crest of the East Pacific Rise in 21°N showing a 350°C hot spring typical of those recently discovered there. The water emerges as a clear homogeneous solution from orifices about 15 cm in diameter at rates of a few metres per second. Rapid mixing with the local ambient seawater induces the precipitation of a variety of minerals from solution. These include sulphides of iron, zinc and copper and several silicates. The 'black smokers' also deposit constructional features — chimneys — of the same materials. These form the conduits emerging from the fields of pillow basalts as seen in the lower part of this picture.

transported by rivers, the much higher salt content of seawater allows for extensive reaction. The composition of the original seawater is radically transformed in the high-temperature zone. The fluxes of dissolved materials into and out of the axis are comparable to those of rivers. Magnesium and sulphate are quantitatively removed, resulting in a sink for the fluvial

J.M. Edmond is in the Department of Earth and Planetary Sciences at the Massachusetts Institute of Technology.

Lonsdale⁹ had found evidence in 1977 of active springs in the area of high heat flow in the Guyamas Basin in the northern part of the Gulf of California (see *News and Views* 289, 9; 1981). This portion of the ridge axis is buried under several hundred metres of sediments principally supplied by the Colorado River. Subsequent Deep Sea Drilling Holes (leg 64) showed the presence of basaltic sills in the sediment column, some of them still hot¹⁰. In the summer of 1980 a Deep Tow survey yielded photographs of active hot springs; sulphide minerals were recovered by dredging and the plastic liner of a core barrel melted at a depth of several metres in the sediment. Recovered cores were lithified and contained very high concentrations of light hydrocarbons produced by thermal cracking of buried planktonic debris¹¹. Venting of very hot waters is clearly occurring despite the sealing effect of the thick sediment blanket.

Galápagos-type hydrothermal mounds were discovered in Deep Sea Drilling Program holes (leg 60) on the flanks of the back-arc spreading centre in the Marianas

Basin¹². An extinct massive sulphide deposit was found at a ridge-transform intersection on the Galápagos ridge during dives by *Alvin* at the beginning of 1980¹³.

The joint US-French programme on the East Pacific Rise also met with success. In the summer of 1980 an expedition on the Jean Charcot using the 'Seabeam' high-resolution bathymetric mapping array and the RAIE towed camera system found active sulphide deposition at several locations. Numerous samples were obtained by dredging¹⁴. Major diving campaigns are planned in the Eastern Pacific in 1981 using both US and French submersibles. □

Monitoring Mount St Helens

from M. McCormick

IN November, just six months after the 18th May 1980 cataclysmic eruption of Mount St Helens, Washington, a multidisciplinary group of researchers brought their various viewpoints and data to Washington DC*. Among the problems they discussed were: Was the eruption going to affect climate or local weather? What are the important measures describing a volcanic eruption — height of the cloud, sulphur content, lava flow, or other factors? How did Mt St Helens compare with past volcanic eruptions? The uniqueness of the meeting came from the variety of disciplines and research areas represented. Volcanologists, geologists, biologists, meteorologists, atmospheric chemists and physicists, climate modellers, remote sensor specialists and geochemists were all working together.

When Mt St Helens erupted, there existed, for the first time, sufficiently sophisticated technology to measure the global movement and enhancement of stratospheric aerosol mass loadings. This, coupled with a mature modelling capability, a number of programs specifically set up to measure volcanic effluents and stratospheric aerosol radiative characteristics, and a readily accessible volcano, all helped to make this

volcano and its eruptions the best documented in history.

The NASA orbiting satellites SAM II (Stratospheric Aerosol Measurement) and SAGE (Stratospheric Aerosol and Gas Experiment), developed specifically for the global measurement of stratospheric aerosols, were important new sources of information. Their international ground truth programs helped drive the development of a number of new lidar systems which were in operation at the time of the eruption. These lidar systems, specifically designed for stratospheric aerosol measurements, are in Japan, West Germany, Italy, France, and the US. They were complemented by programs that used aircraft platforms and a number of *in situ* sensors — for example, the NASA ACE (Aerosol Climatic Effects) program which began the year before and which provided another set of instruments poised and ready to measure stratospheric aerosol parameters important to climate, just as the volcano began its rumblings. The NASA-sponsored RAVE (Research on Atmospheric Volcanic Emissions) is an even newer program whose acceptance was in final negotiations when Mt St Helens erupted on 18 May and which is designed to visit volcanoes close up, and characterize their source function, atmospheric chemistry, and potential impact on climate.

As Mt St Helens is in the US a continuous meteorological network was available so that detailed trajectory analyses could be performed. The Geosynchronous Operational Environmental Satellite-West was also in position to generate electronically pictures of the early heavy plumes and their movements.

Material in the stratosphere has the potential to alter the radiative transfer of solar and terrestrial radiation. This in turn can cause warming or cooling of the surface and atmosphere. The radiative characteristics of the material, such as index of refraction and size distribution, and the underlying albedo, determine the net effect. Model calculations, based on past eruptions and stratospheric aerosol characteristics, have typically shown a warming in the stratosphere and cooling at the surface.

During periods of no major volcanic activity, stratospheric background aerosols are thought to be composed primarily of sulphuric acid and water in an approximate 75/25 mix. Violent volcanic eruptions impart enough energy to the ejecta to penetrate the local tropopause. Once in the stratosphere, the gaseous and ash-like components of the eruption cloud can have a long lifetime as in this region of the atmosphere the rate of cleansing is slow. Thus, material can disperse and spread globally and alter climate. The heavier ash-like or non-volatile particles can fall out faster than the gaseous material (primarily various sulphur gases). The sulphur gases are converted to aerosol particles which are thought to be identical to the background $\text{H}_2\text{SO}_4/\text{H}_2\text{O}$ aerosol. The new aerosols are distributed in a size range about 0.1–0.6 μm which is effective in scattering visible sunlight. The distribution of large particles closer to 1.0 μm is not well known at present but is also important in understanding the radiative transfer through the layers. Based on past data, the lifetime (the time for its mass to reduce to 1/e of its value) of new volcanically-produced stratospheric aerosols at 18-km altitude is about one year. How long it takes for the sulphur gases to convert to $\text{H}_2\text{SO}_4/\text{H}_2\text{O}$ droplets is uncertain, but at the workshop evidence was presented that it takes place quickly, within a month. There is evidence that some conversion even occurred in the erupting plume or in the magma itself. The amount of sulphur gas that is put into the stratosphere becomes crucial to the determination of an eventual effect on climate. Early aircraft measurements showed the aerosol in the vertical column on 18 May to be primarily composed of silicates of larger size below 16 km with sulphuric acid-clad silicates above. Balloon-borne measurements of the material over Wyoming showed a

*The Mt St Helens Symposium was held from November 18 to 21, 1980, chaired by J.P. Friend of Drexel University, Philadelphia and was followed by a workshop chaired by R.E. Newell of MIT.

M. McCormick is Head of the Aerosol Measurements Research Bureau at the Langley Research Center, Virginia.

predominance of non-volatile stratospheric particles early after the 18 May eruption. After about a month, the particles were volatile and similar to background aerosols in their characteristics. Lidar data at two colours and with a measurement at crossed polarizations, were consistent with this conclusion.

Material from the eruption column over Mt St Helens was moved by a system of winds whose direction and speed vary with altitude. A large percentage of the upper atmospheric material was at jet stream altitudes between about 8 km and 12 km, and moved at average speeds of about 20 m s^{-1} circling the globe in an eastward path in as little as 16 days. Higher material moved much more slowly and in sometimes very complex trajectories. For example, material between 15 and 16 km moved eastward, crossing the eastern US coast on 23 May, and reaching Europe no later than 5th June. The material above 20 km was above the wind reversal, and moved westward at an average speed of about 6 to 8 m s^{-1} . Local radar and other remote sensors showed this material reached at least 23 km and travelled around the globe in about 56–70 days. Ground-based lidars tracked this upper altitude material as it crossed westward from country to country.

Most of the radiative models that determine temperature changes for an assumed set of aerosol radiative characteristics describe the temperature change that is caused by a certain mass of new aerosol. The determination of mass, therefore, is very important in estimating the temperature change. Both SAGE and lidar data have been converted through optical modelling to aerosol mass and used to determine the mass added to the background stratosphere. SAGE data yielded a value of 0.25 to 0.5×10^6 metric tons and lidar 0.4 to 0.6×10^{10} metric tons. These calculations are for July when the material began to disperse, affecting the entire Northern Hemisphere. SAGE's 'global eye' showed the material to be most highly concentrated at latitudes greater than 50° N . A normal back-ground hemisphere contains about 0.25×10^6 tonnes of aerosol and the addition due to the eruption therefore represents an approximate 100 per cent increase. Radiative models predict that this increase, although significant, would only cool the near surface temperature by hundredths of a degree and warm the stratosphere near the peak aerosol concentration at 18 km by a degree. The exact values depend, of course, on the specific aerosol characteristics and are in the process of being determined but will not be great enough to have a significant effect on climate. In comparison, the eruption of Agung on Bali was thought to have introduced about 30×10^6 metric tons into the stratosphere in 1963, causing a reported 0.3° C cooling at the surface and about a 4 to 8° C warming in the stratosphere. □

Will the real Grenville Orogeny please stand up

from Keith Bell

THE PROTEROZOIC remains more of a mystery than any other period of the Earth's history and is currently presenting several tantalizing problems, particularly regarding large-scale crustal movement and the formation of orogenic belts. It is generally considered to be a period (2,500 Myr to about 600 Myr ago) of crustal rifting, shearing and dyke emplacement with major transcurrent lineaments, marking large-scale lateral displacements^{1,2}. Because of this, and the scarcity of ophiolites and greenstone belts, some geologists believe that the tectonic regime during the Proterozoic differed from anything that existed either before or since.

The Grenville Province of Canada is one of the most perplexing of the Proterozoic orogenic belts and the numerous models suggested for its origin reflect not only a great deal of speculation but also a marked lack of detailed field mapping. Although the Grenville belt shows features apparently quite different, at present exposure levels, from Phanerozoic continental margin mountain belts (for example, the virtual absence of linear belts of basic igneous rocks and the presence of late alkaline complexes and carbonatites), it still remains unclear whether the pervasive 1,000 Myr Grenville 'event' developed intracratonically or as a result of a collision event involving plate motion. Geological evidence tends to favour the latter^{3–6}.

In this issue of *Nature* (p.129), Baer draws attention to the significance or lack thereof of the 1,000 Myr date for the Grenville 'event' and proposes not one but two orogenies, an earlier one at about 1,100 Myr and a later one at about 950 Myr. Reflected in this paper are many of the problems inherent in the interpretation of geochronological data from polymetamorphosed terranes and the difficulties involved in placing constraints on the so-called Grenville Orogeny.

Although generalization about discordant age patterns in orogenic belts is difficult, most can be attributed to differences either in the temperatures at which the daughter nuclides become 'frozen' into the system during cooling, or in the abilities of different minerals to become open systems to the various daughter nuclides during thermal overprinting. Because of the relative ease of argon migration out of most systems, it is difficult to distinguish slow cooling from overprinting solely on the basis of K–Ar dates. The geological interpretation of the data often depends on the degree of discordancy. According to Baer, the 150 Myr

Keith Bell is Professor of Geology at Carleton University, Ottawa, Canada.

gap between the 'younger' K–Ar and the 'older' U–Pb and Rb–Sr dates from the Grenville Province is too long to be explained by slow cooling and his preference lies with a metamorphic overprinting at about 950 Myr. Others, however, take the opposite view^{7,8}. Although Baer's interpretation of the length of time and the comparison of K–Ar dates with those from other systems might be open to criticism, at least two events can be proposed solely on the basis of the U–Pb and Rb–Sr dates.

Baer's conclusions pose two major questions — what do we mean by the term Grenville Orogeny, and how many events have affected the Grenville Province? The original subdivision of the Canadian Shield into areas affected by distinct orogenies (Kenoran $\sim 2,500$ Myr, Hudsonian $\sim 1,740$ Myr, Elsonian $\sim 1,400$ Myr, Grenvillian $\sim 1,000$ Myr), using the mean value of many K–Ar mineral (mainly mica) dates⁹, successfully outlined large regions of the Shield that had experienced similar terminal thermal histories. But what do these ages really mean? If the term 'orogeny' is used in the sense of epeirogenesis, then the argon dates can be interpreted as dating the time of uplift and cooling, an event which is sometimes, but not always, substantiated by sedimentary sequences of the same or slightly younger age. However, there is no good reason to assume that crustal movements are synchronous both across and along the length of an orogenic belt. Fault-bounded crustal segments ('zones', 'domains') that are now recognized in many orogenic belts of different ages (for example, the Appalachian and Hudsonian orogenies)^{10,11} appear to have had their own distinct thermotectonic histories which may differ from one another by some tens of millions of years. The time of cooling to relatively low blocking temperatures, such as those for argon in micas, can thus vary considerably within a single orogenic belt and because of this it is no longer acceptable to define an orogeny solely on the blanketing together of large numbers of K–Ar dates. The term 'orogeny' in its present usage, in any case, means something more than simple uplift and encompasses the more geologically significant processes of folding, metamorphism and intrusive activity.

The resolution of events in polymetamorphosed terranes requires both isotopic data from two or more radiometric systems and good geological control based on sound field mapping. Questions such as 'Are the dated bodies pre-, syn- or post-tectonic?' and 'How many foliations can be observed in the field?' will have direct

bearing on the interpretation of the isotopic data. The real problem is relating isotopic to geological events, although this may be impossible either because the geology is not known in sufficient detail or because the isotopic event has no visible expression in the rocks themselves.

Unravelling the extremely complex history of the Grenville Province is difficult because the geology of the belt is poorly understood. Some parts have never been mapped at other than the 1:1,000,000 scale although those mapped in detail have yielded rich rewards. A well defined stratigraphy in the relatively low-grade Hastings Basin region demonstrated a major unconformity that can be correlated over 2,000 km², separating a younger psammitic, pelitic and carbonate sequence (the Flinton Group) from an older volcanic, sedimentary and igneous terrane. The known field relationships coupled with the isotopic data pinpoint the deposition of the Flinton succession to between 1,050 and 1,080 (± 25) Myr ago. Furthermore, three deformations (including the one that produced the prominent north-east-trending structures) and an accompanying regional metamorphism all post date 1,050 Myr (ref. 12). Although this represents a fairly small chapter in the history of the Grenville Province, it does emphasize the need for assigning both structural and stratigraphical positions to the various sedimentary and metavolcanic units within the belt and relating them to existing or new isotopic data.

The history of the Grenville Province is much more complicated than that discussed by Baer whose compilation deals with only the last two hundred million years or so. Both geological and isotopic evidence demonstrate its continued tectonic overprinting extending back into the Archaean, including the effects of both the Hudsonian and Elsonian orogenies¹³.

Recent whole-rock Rb-Sr isochrons indicate a granulite facies event at about 1,430 Myr and perhaps two magmatic events at 1,250 and 1,120 Myr from a relatively restricted area of the belt^{14,15}. The questions now remain of how many orogenies have affected the Province and which, if any, should be designated the 'Grenville Orogeny'. This sort of problem is not restricted to the Grenville Province alone. Magmatic and metamorphic events from the Saskatchewan segment of the Churchill Province at 2,430, 1,880, 1,740 and 1,560 Myr have recently been recorded by U-Pb zircon and whole-rock Rb-Sr studies^{16,17}. What then is the age of the Hudsonian Orogeny?

Despite a case having been made for using the term 'Grenville' only in a stratigraphical sense¹⁸, most workers would probably like to use it more generally or even as a specific name for one of the orogenies. If one takes the latter approach, the widespread event at about 1,050 $\pm$ 50 Myr that produced or was superimposed on major north-east-trending structures is a likely candidate. It has all the hallmarks of a well defined orogeny, has been substantiated by more than one radiometric method and is fairly widespread throughout the central part of the Province. An appealing alternative proposes the term 'Grenvillian orogenic cycle', analogous to the Appalachian orogenic cycle that includes the Taconian,

Acadian and Alleghanian orogenies. Already two orogenies, the Elzevirian and the Ottawan have been proposed.

The period from 1,150 to 1,000 Myr ago was undoubtedly a geologically active one, not only in the Grenville Province, but elsewhere in the Canadian Shield. Widespread basic magmatism (Logan sills and Keweenaw lavas in the Lake Superior region, basaltic flows and diabase dykes in the Northwest Territories) and deep-seated alkalic and carbonatitic activity in northern Ontario¹⁹⁻²² suggest a time of large-scale rifting and faulting. Perhaps a closer look at Proterozoic sequences and intrusive bodies outside the Grenville Province may help to pin down more accurately the age of the main Grenville event. Whether such an approach will hold further clues about the origin of the Grenville Province and its deformation or whether such ages are merely coincidental will have to be substantiated by further work.

So the Grenville thorn still remains embedded in the side of the geologist interested in the Proterozoic. Baer's paper, however, certainly forces a re-evaluation of the significance of the $\sim 1,000$ Myr figure so often quoted for the Grenville Orogeny. Whether the two proposed events at $\sim 1,100$ Myr and ~ 950 Myr are geologically significant will only become clear as more detailed field mapping emerges. □

100 years ago

LAST Thursday the Hackney Microscopical and Natural History Society held their annual *soirée*, always a very successful event. Many other similar London societies were represented at the meeting.

An elaborate report upon the opening up of two of the pyramids at the boundary of the Libyan Desert near Sakkara is now published by Prof. Brugsch. The learned professor estimates the matter to be of the most important and valuable kind. At the close of 1880 the entrances to the sepulchral chambers of the three pyramids were laid bare. The ceilings were taken off, and only the two sides, all covered with hieroglyphics, rose from the *débris*. The hieroglyphics point to the reign of Pharaoh Apappus.

An important experiment in electric lighting is about to be made in the City. Hitherto the electric light has been used, as on the Thames Embankment and Waterloo Bridge, in conjunction with gas; but in the City the thoroughfares selected are to be lighted by electricity alone, which will be continued all

night. The experiment is to be continued for a year, at an outlay of about 8000*l*.

It is known that the young horns of the *Cervus maral* (Severtzoff), when they are filled with blood and not yet ossified, are very much prized by the Chinese, who purchase them at the Siberian frontier, paying as much as six to twenty pounds the pair. A very active chase of the maral has therefore always been carried on in Siberia, and since it became rather rare, the Cossacks in the neighbourhood of Kiakhta have domesticated this stag. Now we learn from a communication by M. Polakoff that its domestication has greatly extended in Western Siberia, so that there are herds of seventy head; but the horns of the domesticated deer, as might be expected, have lost a good many of their original qualities.

A stenographic piano has been experimented on by the daughter of the inventor, in the French Chamber of Deputies, the Senate, and to the Municipal Council of Paris, with great success. The system consists of a combination of signs through which every sound is represented. The reproduction is as rapid as speaking, and the same operator can continue the work for hours. The signs used in this system being printed by machinery, the reading is immediate, and can be made by other people than the operator. The State stenographers propose to be trained in the use of the instrument. It is an affair of a few months of practice.

REVIEW ARTICLES

Textons, the elements of texture perception, and their interactions

Bela Julesz

Bell Laboratories, Murray Hill, New Jersey 07974, USA

Research with texture pairs having identical second-order statistics has revealed that the pre-attentive texture discrimination system cannot globally process third- and higher-order statistics, and that discrimination is the result of a few local conspicuous features, called textons. It seems that only the first-order statistics of these textons have perceptual significance, and the relative phase between textons cannot be perceived without detailed scrutiny by focal attention.

THE study of pre-attentive (also called effortless or instantaneous) texture discrimination can serve as a model system with which to distinguish the role of local texture element detection from global (statistical) computation in visual perception. Indeed, the question of whether there are basic elements in perception out of which higher percepts are built, or whether these higher percepts are indivisible, as the Gestaltist psychologists claimed, is still debated. Without using the sophisticated techniques described in this article, it is not obvious, even in the case of pre-attentive texture discrimination, whether local differences between the texture elements directly contribute to discrimination or whether these differences are sensed in a global way only through differences in the statistics of the texture.

A few examples will clarify this problem. For instance, the texture pair in Fig. 1a effortlessly separates into two distinct textures with a sharp boundary between them. This is true even when the texture pair is presented for 160 ms (or less), outside foveal gaze (to prevent scrutiny of the textures element-by-element by scanning eye movements), and when erasure is used afterwards (to prevent scrutiny of the texture pair's after-image by shifts of focal attention). One 'explanation' of this pre-attentive texture discrimination is that the local texture elements in the two textures which have different sizes are processed by local detectors selectively tuned to different sizes; texture discrimination would be directly conveyed by these detectors. Alternatively, one could describe the difference between the two textures globally, by the difference in their first-order statistics, and assume that this statistical difference underlies

pre-attentive texture discrimination. The first-order statistic (or probability distribution) is simply the probability that randomly thrown dots will land on a certain colour (for example, black) of the texture. This first-order statistic is clearly very different for the two textures in Fig. 1a.

Similarly, the effortless texture discrimination in Fig. 1b can be easily explained by the local orientation difference between the elements that constitute the two textures. But again it is possible to describe the difference between the texture pair globally. Here, the first-order statistics of the two textures are identical, but their second-order statistics differ greatly. The second-order statistic (or joint probability distribution) is the probability of the events that the vertices (end points) of randomly thrown 2gons (dipoles or needles) of all possible lengths and orientations will fall on certain colours of the texture (for example, both on black). [The n gon statistic (or n th order joint probability distribution) of an image can be obtained by randomly throwing n gons of all possible shapes on the image and observing the probabilities that their n vertices fall on certain colour combinations.] Obviously, the second-order (or dipole) statistics are very different for the two textures in Fig. 1b. Finally, Fig. 1c is an example in which the textures are defined globally by keeping their second-order statistics different but their first-order statistics identical, yet the resulting discriminable textures also exhibit locally perceivable differences. Here the left half-image is generated by a two-dimensional Poisson process, while the right-half field is generated by the same process, but with the restriction that no two dots can fall closer to each other than some distance ϵ . A local basis for texture

Fig. 1 Pre-attentively distinguishable texture pairs based either on global statistics or local conspicuous elements, or both: a, with different first-order statistics and difference in element size; b, with different second-order statistics and different element orientation; c, with different second-order statistics that result in short neighbouring dots (dipoles) of critical size that can occur only in one half-field. (From B.J. *et al.*¹⁰.)

Fig. 2 Pre-attentively indistinguishable texture pairs with identical second-order but different third- and higher-order statistics: *a*, composed of randomly thrown similar micropatterns and their mirror images, respectively (from B.M. *et al.*¹⁰); *b*, composed of dual micropatterns, as described in Fig. 3*b* (from B.J.¹⁶); *c*, composed of dual micropatterns as described in Fig. 3*b* (from B.J.¹⁶).

Fig. 3 The four-disk method and its generalization to generate isometric dual micropatterns that when randomly thrown, respectively, yield texture pairs with identical second-order statistics. *a* Depicts the four-disk method of B.J. *et al.*¹⁰. One micropattern is composed of the four identical disks A, B, C and D, such that A is centred on the x-axis, B and C are centric symmetric to the origin, while D is centered on the y-axis. The dual micropattern contains D' in place of D, that is symmetric with respect to the origin of D. The dual micropatterns are isometric, but there exist triangles (ABD) that cannot fall on the dual micropattern (after B.J. *et al.*¹⁰). *b*, Generalization of the four-disk method of four steps B1, B2, B3 and B4, where disk A can be any object with bilateral symmetry across the x-axis. BC disks can be replaced by any centric symmetric object, and D and D' can be any objects with bilateral symmetry across the y-axis, and centric symmetric to each other (after Caelli *et al.*¹³).

discrimination exists if one considers feature detectors with receptive fields (of ϵ or smaller extent) as are found in the visual system of vertebrates¹⁻⁴. Texture segregation could be explained by the frequent stimulation of these detectors in the left field, whereas no such detectors are activated in the right field.

These examples indicate that effortlessly discriminable textures with different second- or first-order statistics—which include most, if not all, natural textures—also seem to differ locally. So whether the pre-attentive visual system merely detects the occurrence of certain local features that are present in one texture and absent in another, or analyses some global statistical parameter that distinguishes these textures is still undecided. At this point, some readers might favour the theory of feature detectors, influenced in their choice by the dramatic neurophysiological discoveries of such detectors in the visual systems of frog, cat and monkey by such workers as Kuffler¹, Barlow², Lettvin *et al.*³ and Hubel and Wiesel⁴. However, Barlow, who pioneered the notion of a receptive field in neurophysiology², was unable to find psychophysical evidence for elongated receptive fields in human texture perception. He recently studied the detection of one rectangular random-dot array surrounded by another having different first-order statistics⁵ and found, to his surprise, that performance of detection did not change with the aspect ratio of the target rectangle, despite the fact that most receptive fields in the monkey cortex are highly elongated⁶. Indeed, it took 16 years to find evidence that local feature detectors participate in texture perception.

The iso-second-order texture paradigm

Figure 1*a*, *b* and *c* demonstrate that the pre-attentive visual system might process differences in second-order statistics, or just detect conspicuous local differences, or perhaps performs both operations. In 1962, to test the limit of statistical computational capabilities of the pre-attentive visual system, I posed the question: would it be possible to create texture pairs with identical second-order statistics, but different third- and higher-order statistics; and could such iso-second-order textures still be discriminated? The mathematicians Rosenblatt and Slepian solved the first part of this question for Markov processes⁸, and in probing the second part of the question, I observed that iso-second-order Markov textures of densely packed stochastic dot arrays were usually indistinguishable without scrutiny⁷. Recently, a new class of two-dimensional, non-Markov stochastic dot textures has been created by Pratt *et al.*⁹, and these were also indistinguishable when their second-order statistics

agreed. From these observations one could conjecture that "the pre-attentive textural system cannot globally compute third- or higher-order statistics". This will be called the 'modified Julesz conjecture'. (The original Julesz conjecture, which hypothesized that "iso-second-order textures are indistinguishable", has been disproved and will be discussed below.)

The main problem with these indistinguishable iso-second-order stochastic dot textures is that they are also locally indistinguishable. It would be more convincing to test the modified Julesz conjecture using iso-second-order texture pairs whose elements are conspicuously different yet as textures are indistinguishable. Recently I and my co-workers¹⁰⁻¹⁴ have succeeded in generating several classes of iso-second-order texture pairs that are globally (that is, as textures) indistinguishable but locally (that is, their elements) can be discriminated. Figure 2a, b and c demonstrate three such texture pairs.

The texture pair in Fig. 2a is composed of identical non-overlapping elements ('R') and their mirror-images in all possible random orientations. Such texture pairs, as I and my co-workers¹⁰ have shown, have identical second- but different third- and higher-order statistics. (Indeed, when one of these textures is printed on a glass sheet, the other side shows the mirror-image texture, and obviously the dot and dipole statistics must agree, but the triangle statistics differ.) The texture pair in Fig. 2a is sufficiently indistinguishable that it is unlikely, without prior prompting, that one would suspect that this texture pair is not a single coherent texture. One has to scrutinize the textures element by element and perform a 'mental rotation' in the Shepard and Metzler sense¹⁵. Indeed, even when the pair of elements is presented in isolation, the two elements cannot be discriminated in a 160-ms brief flash followed by erasure if they are oriented far from parallel.

Figure 2b depicts an even more interesting case. This iso-second-order texture pair and many others were generated by the generalization of the four-disk method described by myself and my co-workers¹² as developed by Caelli *et al.*¹³. Figure 3 legend describes how the four-disk method and its generalization work. One can prove the geometry that the micropattern composed of the four disks ABCD, and its partner composed of the disks ABCD' are isometric: to any two points (dipole)

selected in one micropattern there exists a corresponding dipole in the dual micropattern. Although these dual dipoles usually have different orientations, the textures formed by the random throwing of the micropatterns in all orientations result in identical dipole statistics. The generalization of the four-disk method is as follows. One can easily verify that disk A can be chosen to be any shape with bilateral symmetry to the x-axis. B and C disks can become any shape with centric symmetry through the origin, while D and D' can be replaced by any shape with bilateral symmetry across the y-axis and equally distant from the origin. The dual micropatterns composed of these three forms again are isometric. However, there are triangles whose three vertices will fall on one micropattern, but not on its dual micropattern. Thus, the texture pair in Fig. 2b has the same second-order, but different third-order statistics. Here the elements of the two indistinguishable textures are pre-attentively indistinguishable although in this case with focal attention they can be easily told apart. After all, one would expect that simple cortical units whose elongated receptive fields match the rectangles in these texture elements should differentially fire for zero, one or two X's being contained in these rectangles. That no textural discrimination is obtained suggests two possibilities: (1) differences in third- or higher-order statistics are not processed; and (2) the output of local feature analysers is linearly averaged. The latter statement refers to the observation that areas covered by rectangles containing only single X's when linearly averaged have the same contribution as rectangles containing zero or two X's when these occur with 0.5 probability and one assumes that the simple cortical units are themselves linear.

Figure 2c is perhaps the most instructive example. It is also generated by the technique described in Fig. 3b. Here the indistinguishable iso-second-order texture pair is composed of dual elements, respectively, that in isolation are pre-attentively discriminable. Thus, when the dual elements are briefly flashed (followed by erasure) and the two elements placed 6 deg arc apart (3 deg arc from the fixation point) they can be discriminated, regardless of their orientations. The lack of texture discrimination in Fig. 2c is rather unexpected. If one were to assume that Kuffler units and elongated blob detectors of the Hubel and Wiesel type are involved in perception—as attested

Fig. 4 Iso-second-order texture pair generated by the four-disk method: a, just below threshold of pre-attentive texture discrimination (from B.J. *et al.*¹⁰); b, well above threshold. Pre-attentive texture discrimination is based on local conspicuous features of quasi-collinearity of disks. (From Caelli and Julesz¹².)

to by the fact that the 'open' and 'compact' dual elements can be discriminated—it is rather surprising that pools of such detectors (differentially tuned to the larger open and smaller compact elements) are not utilized in pre-attentive texture discrimination. This problem will be resolved in the following sections.

It had been shown that iso-second-order textures exist that are indistinguishable globally even when locally their elements are either attentively, or even pre-attentively, distinguishable. Because the second-order statistics determine the autocorrelation function, and the Fourier transform of the autocorrelation function is the power spectrum, these iso-second-order textures have identical autocorrelation functions and identical power spectra. Thus, the pre-attentive visual system ignores the phase (position) spectrum that is so conspicuous when the elements are viewed by focal attention. This implies the operation of two visual systems, as has been suggested by many workers in the fields of attention and cognition. The attentive system uses focal attention scanned serially. The pre-attentive system uses distributed attention that is mediated by a parallel process. The insensitivity of pre-attentive texture perception to the position of texture elements directly implies a parallel system.

The role of local elements in iso-second-order texture discrimination

The existence of many indistinguishable iso-second-order textures has established that the pre-attentive visual system is unable to process statistical information beyond the second order. The next question is whether iso-second-order texture pairs do exist that yield pre-attentive texture discrimination. If they do, such texture discrimination must be the result of local features. As we have seen that many seemingly conspicuous features do not yield texture discrimination in the iso-second-order statistical constraint, those local features that might yield texture discrimination should be very special ones. They should be regarded as the basic elements of pre-attentive perception, and I have named such hypothetical elements 'textons'¹⁶.

Indeed, in 1978 several new iso-second-order texture classes were discovered that yield strong discrimination based on very conspicuous local features. The first was discovered by Caelli

and myself¹² using the four-disk method given in Fig. 3a. In Fig. 4a a case is shown (using the dual micropatterns shown in Fig. 3a) that is just below the threshold of pre-attentive texture discrimination, although the open and closed texture elements in isolation are pre-attentively discriminable. However, it was possible to open up the open elements further so that the four disk micropatterns became quasi collinear (while keeping the dual elements still 'closed'). As shown in Fig. 4b, presenting the quasi-collinear features in only one texture region resulted in strong pre-attentive texture discrimination. This local feature might be visually extracted by local detectors tuned to elongated blobs (of given width, orientations and aspect ratios).

Several other iso-second-order textures have since been found that yield pre-attentive texture discrimination^{12-14,16-18}. In each case, pre-attentively discriminable local conspicuous features such as 'closure', 'corner', 'connectivity' and 'granularity' were prominent. Figure 5a, b and c show a few typical iso-second-order texture pairs that yield pre-attentive texture discrimination.

Figure 5a and b were obtained by the generalized four-disk method of Fig. 3b, and discrimination seems to be due to the conspicuous local features of closure and connectivity, respectively. Figure 5c is an iso-third-order (hence also iso-second-order) texture pair created by a new stochastic process of Julesz, Gilbert and Victor¹⁴ which shows that, contrary to what might be believed, perceived granularity need not be determined by the power spectrum, nor even by the second- and third-order statistics but can be a fourth-order property! Here again, as in the case of quasi-collinear disks, it seems that elongated blobs of different widths, length and orientation, and perhaps of different first-order statistics in small, local neighbourhoods are the local conspicuous features yielding texture discrimination.

The role of terminators in texture discrimination

Only the quasi-collinear structures (line segments) and elongated blobs in general have so far been identified as textons. Are other conspicuous local features such as closure, corner and connectivity (Fig. 5a, b) also textons? Fortunately, I have recently found that this is not so¹⁶. In one experiment, dual

Fig. 5 Discriminable iso-second-order texture pairs based on local conspicuous features of: a, 'closure' (from Caelli *et al.*¹³); b, 'connectivity' (from B.J.¹⁶; a and b were generated by the method described in Fig. 3b); c, 'granularity'. This texture pair has identical third-order (hence identical second-order) statistics (from B.J. *et al.*¹⁷). The small squares in the first row and middle column are selected black and white at random while each 2×2 square left of the middle column contains even numbers of black squares and right of the middle column contains odd numbers of black squares. However, two basic local features (textons) suffice to explain these differences. In c textons are elongated blobs of different sizes, while for a and b it is the difference in the number of end-of-lines (terminators) of the dual elements that yields texture discrimination.

Fig. 6 Demonstration that if the number of terminators (end-of-lines) agrees, then in pre-attentive texture discrimination their exact positions are ignored. This texture pair is indistinguishable in spite of the fact that the open/closed and connected/unconnected features are juxtaposed in the dual elements; however, line segments and the number of terminators agree.

texture elements were selected in which open/closed and connected/unconnected features were simultaneously juxtaposed (insert in Fig. 6). When these formed texture pairs they could not be pre-attentively discriminated from the surround (Fig. 6). One might suspect that the texture pair in Fig. 6 is indistinguishable (similar to the indistinguishable pair in Fig. 2c) because, in addition to having the same line segments, the number of the end points (terminators) of these line segments is also the same in the dual texture elements. Furthermore, the fact that the texture pair in Fig. 6, composed of 'S' and '10'-shaped elements, is indistinguishable, also shows that the exact position of the terminators is not perceived pre-attentively.

Indeed, if one inspects the discriminable iso-second-order texture pairs in Fig. 5a and b, the basis of discrimination can be seen to be the difference in terminator number. The pre-attentive visual system, evidently, cannot determine the location of terminators, but can count their numbers (or density) or their first-order statistics. Thus, the putative textons of corner, closure and connectivity can actually be simply described by differences in terminator numbers.

Therefore, besides colour, there are two additional texton classes: elongated blobs (of given orientation, width and aspect ratio) and their terminators. Pre-attentive texture discrimination is based either on the difference in the textons or the difference in the first-order statistics (or some parameter defined by the first-order statistic, such as density or standard deviation) of the textons.

Thus, the original Julesz conjecture has been refuted: there are iso-second-order textures that can be discriminated. However, the modified Julesz conjecture seems to hold: the pre-attentive textural system cannot compute statistical parameters higher than second order. Therefore, discrimination

in iso-second-order textures involves differences in local conspicuous features, called textons.

Interaction between textons

One can even strengthen the modified Julesz conjecture by raising the possibility that the pre-attentive textural system globally cannot even compute second-order statistical parameters, but can evaluate only the first-order statistics of textons. If this were the case, then for the pre-attentive system the interactions between textons would be simple, based on some first-order statistical parameters.

An experiment, depicted by Fig. 7 (and published here for the first time) suggests such a possibility. In Fig. 7a the same micropattern comprised of a 4×4 dot array of randomly selected 8 white and 8 black dots is repeated many times horizontally and vertically with an 8-dot period (leaving 4-dot-wide blank gaps between the micropatterns). This periodically covered area is flanked on two sides by an area of densely packed random dots of black and white. Figure 7b is derived from Fig. 7a by filling the blank gaps between the periodic micropatterns with densely packed black and white random dots. The texture pair in Fig. 7b (composed of the area with periodic micropatterns and the neighbouring random area) have identical first-order statistics but very different second-order statistics (and very different autocorrelations). Nevertheless, the texture pair appears indistinguishable. On the other hand, if the 4×4 dot micropattern contains a texton (consisting of 8 white and 8 black dots forming stripes) as shown in Fig. 7c and d (with and without blank gaps between the periodic micropatterns, respectively), Fig. 7d yields strong texture discrimination, based on the dense occurrence of textons that are practically absent in the other texture. Indeed, the largest difference in the autocorrelations between the periodic and aperiodic textures occurs at the 8-dot periods, and this difference is the same for the indistinguishable texture pair in Fig. 7b and the strongly distinguishable one in Fig. 7d. These examples clearly indicate that texture discrimination is not the result of differences in second-order statistics, but is based on density changes in textons. Caelli and myself¹⁹, who studied discrimination of texture pairs composed of dot pairs (dipoles) having different orientational ranges, could predict perceptual performance based on the first-order statistic of dipole orientation alone.

It is interesting that if texture elements and their dual partners differ in their textons, even a single element can be pre-attentively perceived as being different amidst many iso-second-order dual partners (Fig. 8a).

Recently, Burt and I became interested in the interactions between textons, or interactions between the first-order statistics of different textons²⁰. We were particularly interested in cooperative interactions, and to this end we tachistoscopically presented two or more target micropatterns embedded in iso-second-order dual partners, either dispersed or grouped, as shown in Fig. 8a and b. We found that if the critical (unshared) texton belonged to the target micropattern and not the surround, there was no cooperativity. The dispersed and grouped conditions were equally detected, and probability of detection increased with the number of target micropatterns (that is, with the number of the critical textons). Also, probability of detection was greater when the critical texton belonged to the target micropattern instead of the surround. In another texture paradigm, Beck²¹ noted that the presence of features (textons) in the target is more perceptible than their absence.

If the critical texton(s) are absent from the target micropatterns (and thus belong to the surround), then the grouped condition is better perceived than the dispersed. However, this 'cooperativity' is of a rather simple kind. If we assume pools (layers) of similar textons corresponding to various retinal positions, then the presence of a critical texton in a target micropattern will cause activity in the critical pool (and increased activity with many targets, according to their number) regardless of whether these textons are dispersed or grouped. However, the absence of critical textons in the target micropatterns means

that these textons belong to the micropatterns in the surround, and densely stimulate the corresponding texton layer. To be certain that a texton-free area is not a chance fluctuation, this area must be significantly larger than the mean distance between the micropatterns of the surround. Obviously, grouped target micropatterns assure a much larger texton-free area than do dispersed ones.

Finally, we also observed that with long practice, involving several hundred trials, some indistinguishable iso-second-order texture pairs (such as Fig. 2c) could become pre-attentively discriminable. This might seem contradictory to the recent cognitive studies of Treisman²², who conjectured that conjunctions of features (she used colours and shapes) cannot be pre-attentively perceived, even with practice, but require serial, element-by-element search. The research reported here agrees with her findings. Only disjunctive texton groups (that is, differences in textons) can be perceived pre-attentively (that is, as a parallel process, regardless of element number). The reason the conjunctions of textons that form the dual elements in Fig. 2c can be learned might be that these open and closed elements can have different stimulatory effects on elongated blob detectors,

which are themselves textons. Their detection escaped attention before the task was mastered.

Textons and Marr's 'primal sketch'

It was only after 18 years that I and my co-workers discovered how the simple, complex and hypercomplex cortical feature detectors of the neurophysiologists would correspond to the texton detectors of elongated blobs and their terminators. Thus, it took that long to overcome the initial scepticism, and show that the feature detectors of the neurophysiologist could be utilized in pre-attentive perception. Marr²³, within the framework of artificial intelligence (machine vision), proposed his 'primal sketch' model based on local intensity changes across edges, elongated blobs (lines) and end-of-lines, and their first-order statistics. In essence, the input is spatially filtered and convoluted with masks of given shapes, widths and orientations, similar to the 'Mexican hat function' shape receptive fields of simple cells of Hubel and Wiesel⁶. Marr also introduced inhibition between such simple units (particularly of perpendicular

Fig. 7 Demonstration that the pre-attentive textural system cannot process globally differences in second-order statistics, and only first-order statistics of textons yield texture discrimination. *a*, Periodically repeated 4×4 dot micropattern that does not contain textons, flanked by randomly dotted areas. *b*, Same as *a*, except that the blank gaps between the periodic micropatterns are filled with random dots. The second-order statistics are very different between the area composed of periodic micropatterns and its random neighbour, and yet they appear indistinguishable. *c*, Same as *a*, except that the 4×4 dot micropattern contains textons of periodic stripes. *d*, Same as *c*, except that the noise insertion described in *b* is carried out. Now strong texture discrimination is experienced based on the dense occurrence of textons that are missing in the neighbouring area.

Fig. 8 Demonstration that texton differences can be pre-attentively detected even if the target micropatterns are dispersed within many dual elements as in *a*; in *b* a few target elements are grouped. With centre fixation and briefly flashed (using erasure), the dispersed and grouped case yields identical detection when the unshared textons belong to the target.

units) giving rise to terminators, trying to emulate all the known feature detectors of the neurophysiologists, and devised algorithms that would emulate pre-attentive vision. Thus, Marr was the first to stress the role of terminators in texture perception. However, he went a step further and introduced 'place tokens', higher-order collections of blobs (lines) based on several grouping operations that do not depend on semantic content. Space does not permit a review of this important model, but let me quote Marr (ref. 23, p. 510): 'Julesz (1975, p. 43) mentioned in an aside the possibility that texture vision may rest on 'first-order statistics of various simple feature extractors' but this idea requires the concept of the primal sketch and of recursively applied grouping before it can be brought into fruition.' Although Marr's primal sketch model goes beyond texture perception, into pre-attentive vision and beyond, neither he nor neurophysiologists or researchers in artificial intelligence could have guessed that in texture discrimination only the number of terminators has perceptual significance and that their position is ignored. Similarly, without careful psychological research, one cannot guess how real and virtual dipoles (between two place tokens) affect perception. For example, the primal sketch model regards them as equal, which led to incorrect predictions in texture discrimination as shown by Schatz²⁴. Also, the finding that in texture perception only three or more quasi-collinear place tokens act as a real line shows the importance of perceptual experiments¹⁶. It remains to be seen whether, besides the three texton classes, some other textons will be found in pre-attentive texture discrimination—the more complex place-tokens of Marr. On the other hand, anyone who wants to go beyond texture perception should carefully study Marr's discerning ideas.

Obviously, artificial intelligence, neurophysiology and psychology can aid each other, and the fact that the search for textons led to findings that agree with ideas and discoveries in artificial intelligence and neurophysiology is most gratifying.

Conclusion

It was shown that contrary to the Gestaltists' belief, a highly global percept, texture, can be decomposed into elementary

units, the texton classes of colours, elongated blobs of specific widths, orientations and aspect ratios, and the terminators of these elongated blobs.

One might ask whether sinusoidal gratings, so popular in vision research, could be used in texture perception. After all, the detection of compound sinusoidal gratings does not depend on phase (if the ratio of the gratings is 3:1 or higher), as shown by Graham and Nachmias²⁵. This phase independence at threshold of detection, however, should not be confused with the phase independence of suprathreshold discrimination often found in iso-second-order textures. While textures with identical second-order statistics have identical power spectra, the converse is not true. One cannot profitably study textures having only identical power spectra, because changes in phase between sinusoidal grating components dramatically change the first-order statistics, and thus give rise to texture discrimination for trivial reasons. Furthermore, global Fourier analysis cannot reveal the occurrence of local textons, particularly terminators²⁶ (also implied by the demonstrations of Fig. 7 and ref. 28).

Thus, through the iso-second-order texture paradigm we can restrict the global computational powers of pre-attentive perception and identify local conspicuous features, the textons. Whatever the final number of these texton classes will be, it is evident that for texture discrimination the Gestaltists' view has not been corroborated: the global percept of texture was found to be decomposable into more basic elements. Only if pre-attentively discriminable texture pairs were to be discovered, with its elements (or local aggregates of these elements) found to be pre-attentively indistinguishable, would my modified conjecture be refuted.

This article was restricted mainly to research based on the iso-second-order texture paradigm. The reader interested in more conventional texture research, particularly in the more complex problems of textural grouping and recognition, and in practical problems such as that of automating the search for malignancy in clinical tissues, might find additional references in ref. 27.

In conclusion, let me draw an analogy to the phase-transitions of physics, in which symmetry (invariance) laws and the breaking of these symmetries prevail. Textons in pre-attentive perception obey such a symmetry law. They seem, within limits, to be invariant under positional and scaling transformations. These symmetries of textons cannot be broken by pre-attentive and peripheral vision, as the 'coupling' that locks textons in their proper positions is missing (as if the 'attentional temperature' in these systems were too high). Only by inspecting areas where the densities of textons differ, thus switching to focal attention, can our visual system break the texton symmetries. Only within a small disk of focal attention are the textons coupled (as if this disk were 'cooled' below a critical temperature), permitting the formation of higher percepts (thus enabling us to distinguish, say, an R from its mirror image). This analogy mainly serves to pinpoint the major implication of our findings, that most of the single cortical feature analysers (outside foveal representation) might not be connected directly to each other (but interact only in aggregate). This relative phase insensitivity might also account for the apparent poor spatial resolution of our peripheral vision, which, however, is quite acute for textons, particularly end-of lines.

Consideration of the epidemiological evidence on radiogenic lung cancer in uranium miners and of the incidence of the disease generally leads to an upper estimate for the lifetime risk of 10^{-4} cases per working level month for members of the general population.

IN radiological protection, the emphasis is usually on limiting exposure to artificial radiation. Thus, there is a well-established approach to the protection of staff in hospitals from X rays and to the protection of members of the public from radioactive consumer goods or from effluent from nuclear power plants. How one should deal with exposure to natural radiation is less clear.

Human beings have always been exposed to natural radiation both from within and outside the body. The view adopted by the International Commission on Radiological Protection (ICRP) is that exposure to normal levels of natural radiation cannot usually be subject to control, but it is acknowledged that there may be unusual circumstances in which control is desirable¹. The Commission has in mind circumstances in which there is a considerable increase in exposure as a result of human practices or choices of environment.

One of the principal ways in which members of the public receive natural irradiation is by breathing the radon-222 decay products in air. Radon gas is emitted by soil, rocks and building materials, all of which contain the parent radium to some extent. Radon can also be present in water, from which it is readily desorbed. Out of doors, the gas is dispersed in the atmosphere, but it concentrates indoors to a degree dictated primarily by the ventilation rate of the dwelling and the rate of radon input. The solid short-lived decay products of radon grow in rapidly² and, if attached to an aerosol rather than to walls or furniture, are inhaled and irradiate the lung tissues. Lung cancer may result.

Even in normal circumstances, human exposure to radon decay products is substantial compared with other components of the overall exposure to natural radiation. In abnormal circumstances, radon exposure may be dominant and perhaps also unacceptably high. Such abnormal circumstances stem from the use of building materials with relatively high radium content, for example, or the use of domestic water with exceptionally high radon content.

The basis of dose limitation in radiological protection is risk limitation. For example, the dose equivalent limit for workers is set so that the average risk likely to be incurred is comparable with the average prevailing for other workers in industries regarded as having high standards of safety. For members of the public, the level of acceptability of risk is probably an order of magnitude lower. It is important, therefore, to have some information on risk factors for environmental exposure to radon decay products if a system of control is to be considered.

Direct risk information does not exist for environmental levels of radon decay products. It is therefore necessary either to extrapolate from data for occupational exposure or to infer the

risk from the incidence of lung cancer in the wider population. Both approaches are followed here. We have taken care neither to exaggerate the risk nor to overextend the evidence.

Uranium miner data

The only occupational data that can be used for obtaining a risk estimate for lung cancer caused by radon decay products are those from the exposure of underground uranium miners. Although the BEIR report³ does give an estimate of the risk of lung cancer from whole-body external irradiation, this is insufficient for the present purpose. Of the four sets of data on miners, those from Sweden and Canada are considered to be less useful, and we have therefore concentrated on the data from Czechoslovakia and the United States. Information on exposure is given in terms of working level month (WLM), the unit commonly employed in mining. One WLM is defined as exposure for 1 working month of 170 h to a concentration of one working level (WL), where one WL is any combination of short-lived decay products of radon-222 per litre of air that will result in the emission of 1.3×10^5 MeV of α energy during complete decay^{2,4,5}.

Several factors cause the data on miners to be more difficult to use than might at first appear. The average concentrations throughout US mines in the 1940s and 1950s were high (7–15 WL) and mean exposures accumulated over the 1950s and 1960s were about 800 WLM (ref. 6); in the last decade, however, levels were lower by one to two orders of magnitude^{7,8}. Most of the early information on exposure was obtained by the operators, frequently in areas where ventilation problems were known to exist: on the other hand, there was sometimes a tendency for higher exposures to be under-reported. All the measurements on aerosol characteristics, such as particle size and unattached fraction, have been made under modern mining conditions. These conditions include improved ventilation, the presence of diesel smoke (which probably overwhelms other particulates) and the virtual disappearance of the one-man mine. The evaluation of risk is also complicated by the presence of other carcinogens in mine air as well as by the miners' smoking history and their previous experience of hard-rock mining.

The estimates of lifetime risk that emerge from the data available on miners range from one estimate of 21–54 deaths from lung cancer per 10^6 WLM of collective exposure to one of 1,000 or so. Stewart and Simpson (unpublished) and Myers and

Stewart⁹ have evaluated the American and Czech data using various statistical techniques. Their work indicates that the incidence of lung cancer can be accounted for by a linear relationship with exposure, allowing a constant factor for non-radiogenic lung cancers; their estimate is 21–54 lung cancers per 10^6 WLM from the US data¹⁰, but the Czech data imply a risk about three times as great¹¹. The discrepancy is not readily explained. Stewart and Simpson also found a real or apparent threshold in some of the analyses, which suggests that the estimate of risk for low-level exposure may even include zero as a lower bound. (In such cases, Stewart and Simpson used the slopes of the response curves to derive risk factors.) Jacobi¹² also noted the discrepancy between the US and Czech data and proposed a range of 100–500 lung cancers per 10^6 WLM, which is virtually identical with an earlier estimate by UNSCEAR¹³; in neither case is a threshold effect posited. The highest estimate of risk of about 1,000 lung cancers per 10^6 WLM comes from Archer's recent proposal¹⁴.

Whereas it is not possible completely to rule out any of these estimates of the lifetime risk from occupational exposure, our objective is to estimate risk to the general population from exposure to radon decay products in the general environment. In using the data for uranium miners to derive the lifetime probability of fatal lung cancer for members of the public, one must note that there are significant environmental and physiological differences between the two situations. These differences result from the possible contribution to lung cancer induction in mining environments of other dusts and gases, from differences in breathing rates, from differences in equilibrium ratios of the radon decay products, from high as opposed to low concentrations, from differences in smoking habits and from population distributions that differ in age and sex. Although some of these factors may tend in opposite directions, on balance, they suggest that members of the general public may be at a lower risk per unit exposure than miners. For example, breathing rates for a man resting indoors could be two to three times lower than for a man mining, with the concomitant decrease in exposure counteracted to some degree by an increase in the probability of depositing radon decay products in the lung.

We judge from the epidemiological evidence that the most defensible upper bound of the lifetime risk to the general population is 100 deaths from lung cancer for a collective exposure of 10^6 WLM, or 10^{-4} per WLM. This particular factor, although severely rounded to avoid the impression of unwarranted accuracy, can be supported by other indirect epidemiological evidence, which is detailed below, and by an analysis (W. Jacobi, personal communication) of the dosimetry of radon decay products in the manner of Jacobi and Eisfeld¹⁵.

Lung cancer incidence

Most calculations of the exposure of the general population were initially made on the basis of outdoor radon levels. Indoor levels were known to be higher, but it is only recently that an appreciable number of measurements has become available. UNSCEAR¹³ summarized the literature appearing before 1976, and more detailed measurements have since been published^{16–19}. Information on living habits in the Northern Hemisphere indicates that more than 90% of the day is spent indoors, so that indoor exposure is used here to represent total exposure.

The activity concentration of radon indoors in the Northern Hemisphere lies, on the average, in the range of 0.5–1 pCi per l. If a value of 0.8 pCi l^{-1} is assumed, some measurements in the United States¹⁶ indicate that this can be converted to a decay product concentration of $\sim 0.004 \text{ WL}$. For 168 h per week of indoor occupancy, the exposure would be 0.2 WLM in 1 yr or 12 WLM in 60 yr. The latter period might be shortened somewhat, but this would not change our general conclusion.

Given this mean lifetime exposure of 12 WLM and the risk factor of 10^{-4} per WLM given above, a maximum lifetime risk of 0.12% is obtained by extrapolating linearly and by neglecting latency and accumulation interval. This is a relatively small fraction of the present lifetime risk of lung cancer (about 4% in the United States), which is largely attributable to cigarette smoking.

Making the reasonable assumption that exposure of the general population to radon decay products has been constant over several decades, one can compare the estimate of 0.12% with the incidence of lung cancer before the effects of smoking became pronounced. There are relatively good data²⁰ on incidence in the United States in 1930 which yield a lifetime risk of 0.1%, roughly 0.15% for males and 0.05% for females. Since not all lung cancers at that time would have been caused by radon, this indirect evidence supports the view that a value of 10^{-4} per WLM is a reasonable upper bound of risk to members of the public.

Quite independently, Cliff and others^{17,18} have studied the relationship between the observed exposure to radon decay products and the observed incidence of lung cancer in British women. Taking an average exposure rate of 0.15 WLM per yr, and assuming a risk factor of 2×10^{-4} per WLM (ref. 6) as well as a 20-yr latency period, they predict a higher incidence of lung cancer than is observed from all causes in women below 40 years of age. This supports the evidence from the United States, and indeed an upper bound of 10^{-4} per WLM for the lifetime risk would not be incompatible with the British epidemiological evidence.

The overall evidence therefore points to an upper estimate for the lifetime risk of 10^{-4} cases per WLM for members of the general population.

Risk estimates compared

It is of interest to compare the risk of lung cancer from exposure to radon decay products with that from external penetrating radiation. On the basis of a linear non-threshold model, and purely for protection purposes, ICRP estimates that the risk factor for external irradiation of the lung alone is 2×10^{-3} per Sv or 2×10^{-5} per rem, where Sv and rem are the new and old units of dose equivalent, respectively¹. Thus, the lifetime risk from an exposure to radon decay products of 1 WLM, namely 10^{-4} , would not exceed that from an external irradiation dose equivalent of 50 mSv (or 5 rem) to the lung alone.

It is difficult, however, to imagine circumstances in the general environment in which the lung alone would be exposed to external radiation: whole-body irradiation is much more likely. The ICRP takes the view that most, if not all, forms of fatal malignant disease and hereditary damage can be induced by exposure to ionizing radiation and that, when all the organs of the body are uniformly exposed, cancer of the lung in particular will account for about 10% of all harmful effects. Thus, the lifetime risk associated with an exposure to radon decay products of 1 WLM would not exceed the overall risk associated with a dose equivalent of about 5 mSv (or 0.5 rem) to the whole body from external radiation.

The annual dose equivalent limit recommended by the ICRP for individual members of the public is in fact 5 mSv.

This review has its origins in an international workshop on radiation protection principles for naturally occurring radionuclides held at Arlington, Virginia, in May 1978 by the Nuclear Energy Agency of the OECD. The authors, who were members of a group considering radon problems, have had a number of subsequent exchanges and discussions on the estimation of risk from this source. Thus the present paper should be attributed to them, even though they had the advantage of the initial group deliberations which included M. Kinoshita. The authors also acknowledge the assistance they received from M. C. O'Riordan.

ARTICLES

Structure, strength, and polarization changes in radio source SS433

R. M. Hjellming

National Radio Astronomy Observatory, Socorro, New Mexico 87801, USA

K. J. Johnston

E. O. Hulburt Center for Space Research, Naval Research Laboratory, Washington DC 20375, USA

VLA observations of SS433 at 1,465, 4,885, and 15,035 MHz between 8 September 1979 and 20 June 1980 show structure with size scales between 0.1 and 5 arc s which changes significantly on time scales of 1–2 weeks. Jets with 8–20% linear polarization are ejected on both sides of the central radio source which is coincident with the optical image, along position angles between 80° and 120° with a mean position angle for ejected material of 100°. Features in linear polarized intensity maps can be identified in four successive epochs spanning 196 days, and the resulting proper motions for identifiable clouds are 0.0088 arc s per day. If the feature velocities are equal to that of the optical emission lines, the distance to SS433 is 5.1 kpc. The position angles of identifiable features correlate well with the known precessing optical jets if one extrapolates back to the time of ejection using the observed transverse speeds. The equipartition magnetic field strengths of 0.001–0.01 G indicate synchrotron lifetimes of 10^9 – 10^{11} s; therefore synchrotron losses are not a dominant factor in the evolution of the extended radio emission. The evolution of radio jets indicates that the relativistic electrons and magnetic fields seen as synchrotron emission may be generated by flows along the rotation axis of the accretion disk of the SS433 star system.

DISCUSSIONS^{1–4} of the peculiarities in the optical emission lines of SS433 together with various theories^{5–7} have established that SS433 has oppositely directed jets of optically emitting material moving with speeds of 0.26c. Variations in the apparent Doppler shifts of emission lines indicate an oscillation in the direction of the jets which can be interpreted as precession of an accretion disk responsible for the weak X-ray emission⁸ and the high velocity flows perpendicular to the accretion disk which

appear as the optically observed jets. The detection of radio emission from SS433 (refs 9, 10) has led us to question whether SS433 has radio jets analogous to those in extragalactic radio sources or double radio sources such as those associated with the strong X-ray source Sco X-1 (ref. 11). We now discuss observations that establish not only that SS433 has radio jets, but that they are linearly polarized with changes in strength, position, polarization, and polarization angle on time scales of 1–2 weeks.

* Green Bank interferometer data (from ref. 12).

Fig. 1 VLA maps at 4,885 MHz. The grid of crosses corresponds to 2 arc s intervals. Position angles corresponding to 80°, 100°, and 120° are marked with solid, dashed, and solid straight lines, respectively. The beam shape corresponds to the 50% contour level for each map: *a*, 8–9 September 1979 with peak of 0.32 Jy per beam and contours at the 95, 80, 65, 50, 35, 20, 12, 8, 5, 4, 3, 2, 1.5, 1, and –1% level; *b*, 16 September 1979 with peak of 0.36 Jy per beam and contour levels as for the 8–9 September map; *c*, 7 December 1979 with peak of 0.71 Jy per beam and contours at the 95, 80, 65, 50, 35, 20, 15, 10, 7, 5, 4, 3, 2, 1.5, 1, 0.5, and –0.5% level; *d*, 7 March 1980 with peak of 0.29 Jy per beam and contours at the 95, 80, 65, 50, 35, 20, 12, 9, 7, 5, 4, 3, 2, 1, 0.7, 0.4, and –0.4% level; *e*, 5 April 1980 with peak of 0.34 Jy per beam and contours at the 95, 80, 65, 50, 35, 20, 10, 7, 5, 4, 3, 2, 1, 0.5, and –0.5% level; *f*, 20 June 1980 with peak of 0.39 Jy per beam and contours at the 95, 80, 65, 50, 35, 20, 15, 10, 7, 5, 4, 3, 2, 1, 0.7, 0.4, and –0.4% level. The restoring beam is denoted by the cross-hatched ellipse and is equivalent to the 50% contour of the map.

The observations

The dates of observation, frequencies, and total flux densities (S_ν) obtained for SS433 with the partially completed VLA from 8 September 1979 to 20 June 1980 are listed in Table 1, together with the 2,695 and 8,085-MHz flux densities for SS433 measured at the same times¹² with the Green Bank interferometer. The VLA observations were taken with different numbers of antennas, ranging from 17 in September 1979 to 22 in June 1980. Bandwidths of 50 MHz were used and system temperatures were roughly 45, 45, and 250 K at 1,465, 4,885, and 15,035 MHz, respectively. Calibration was based on interleaved observations of the point source 1947+079, assuming a position for this source of $\alpha(1950) = 19^h 47^m 40.15^s \pm 0.013^s$ and $\delta(1950) = +07^\circ 59' 35.8'' \pm 0.2''$ and flux densities of 1.15, 1.04, and 0.45 Jy at 1,465, 4,885, and 15,035 MHz, respectively. All the VLA observations listed in Table 1 are consistent with the following position for SS433: $\alpha(1950) = 19^h 09^m 21.274^s \pm 0.013^s$, $\delta(1950) = +04^\circ 53' 54.3'' \pm 0.2''$. This is consistent with the radio and optical position of Kaplan *et al.*¹³ measured near epoch 1979.6. Thus from July 1979 (epoch 1979.6) through June 1980 (epoch 1980.5), the radio position of SS433 has remained centred on the position of the optical image measured at epoch 1979.5.

The radio spectra for SS433 at six different epochs as established by the VLA and Green Bank interferometer data (Table 1) show non-thermal spectral indices of $\alpha =$

$-0.6 \pm 0.1 (S_\nu = \nu^\alpha)$ except for times shortly after flaring, that is, 7 December 1979 and 20 June 1980. Shortly after strong flaring the spectra steepen due to newly accelerated relativistic electrons. On 7 December, 7 March and 20 June there are signs of a turnover at lower frequencies.

The data obtained on 8 and 9 September 1979, when two observing programmes coincidentally included SS433 for different reasons, showed no signs of change. These data were combined in aperture synthesis maps to give radio maps for SS433 on 8–9 September 1979, 16 September 1979, 7 December 1979, 7 March 1980, 5 April 1980, and 20 June 1980. The data obtained on 21 September 1979 were at only 1 h angle and did not yield a useful map. On the last four epochs maps were made at 1,465, 4,885, and 15,035 MHz. Figures 1–3 show the 4,885-MHz aperture synthesis maps for six epochs, in which the

Fig. 2 VLA 4,885-MHz linear polarization vector maps superimposed on total intensity contours selected from Fig. 3. Polarization maxima correspond to the longest vectors with values of: a, 4.6 mJy for 8–9 September 1979; b, 7.6 mJy for 16 September 1979; c, 4.3 mJy for 7 December 1979; d, 2.6 mJy for 7 March 1980; e, 4.3 mJy for 5 April 1980; and f, 3.2 mJy for 20 June 1980.

grid of crosses corresponds to 2-arc s intervals. Figure 1 shows the total intensity maps (Stokes parameter I). Figure 2 displays the linear polarization vectors superimposed on a few total intensity map contours. Figure 3 shows maps of linear polarized intensity. In Figs 1 and 3 the lowest contour levels correspond to the peak 'noise' features in the maps. The noise level in linear polarization is indicated in Fig. 2 by the random vectors outside the vicinity of the SS433 radio contours.

The 4,885-MHz maps in Fig. 1 were processed with the standard mapping and sidelobe correction (CLEAN¹⁴) programmes used at the VLA site. In addition, a self-calibration technique, based on solving for antenna-based phase differences and amplitude ratios between the visibility data and a model derived from the Högbom¹⁴ CLEAN algorithm, was used to improve the dynamic range of the maps. This technique was used for all of the maps presented here. The 4,885-MHz maps in Fig. 1 show that the total intensity structure is predominantly contained within the arc set by the position angles 80°–120°, with a mean value of 100°. The VLA maps produced by Stocke *et al.* (in refs 15, 16) are qualitatively similar. These maps are dominated by a strong central component which usually contains ~75% of the total flux. Noting that the beam shape is identical to the 50% contour levels, there is a substantial

improvement in the maps as the VLA evolved from 14 to 22 usable antennas. The extended structure in these maps is below the 5% contour level. The improved synthesized beam and sensitivity of the VLA made the December 1979 maps greatly superior to the September 1979 maps, and the three maps made in 1980 had even better quality. The September 1979 maps showed signs of extended structure. The 7 December 1979 map was made during a short lull in an unusually strong flaring period that occurred from 7 August to 29 December 1979 (ref. 12). On 7 December 1979 there was twice the total radio flux of the other maps in Fig. 1, and the 'extra' flux appeared as a combination of more flux in the central source and a strong bulge of emission to the east which contains twice the flux of other extended features for the maps at other epochs. This bulge is probably due to plasma ejected during this intense period of flaring as it takes ~80 days for plasma at a speed of 0.26c to travel 1 arc s at a distance of 3.5 kpc. As the maps in Fig. 1 show drastic changes in structure, the time scale for perceptible changes in extended structure is almost certainly 1–2 weeks.

Radio jets on both the eastern and western sides of the central radio source are most easily seen in Fig. 1d–f. On 7 March most of the extended emission to the east shows a variation of position angle with distance from the central source. The same pattern continues through the April and June 1980 maps, with distinct changes in the structure from one map to the next. However, outward motion and the consequent determination of proper motions are best seen in the linear polarization maps of the SS433 radio jets. In the 7 March and 5 April maps in Fig. 1 the extended structure can be described in terms of three types of features: (1) extended emission located on both sides of the central source with roughly 3 arc s separation and a position

angle of 88° , (2) low level emission with size scales up to 6 arc s, with a full range of position angles between 80° and 120° , and (3) a clearly identifiable outer extrusion on the east side with position angle near 80° . In the 20 June map there is only the central source and extended structure evolved from expansion of the structure seen in March and April.

In Fig. 2 the 4,885-MHz polarization vectors are superimposed on a few total intensity contours. In all cases the polarization of the total flux is of the order of 1% or less, but much higher percentages (8–20%) of polarization are seen in the extended features of the jets. This is most clearly seen in the later four maps in Fig. 3, where the linearly polarized intensity maps are shown. In Fig. 3 X shows the location of the central radio source coincident with the optical image of SS433. The very one-sided linear polarization map for 7 December clearly indicates a result supported by succeeding maps—newly produced structures of relativistic plasma are highly linearly polarized once they are more than a few light days from SS433.

Because of this, the linear polarized intensity maps are both indicators of ordered magnetic field regions, and good indicators of the variable 'jet' structure of SS433.

The changes in polarization angles are very striking in Fig. 2. Figure 3 shows that in the September and December maps the polarization is dominantly one sided. This was during a period of heavy flaring activity¹². Between 7 March and 12 June 1980, no strong flaring occurred¹² but there was an onset of flaring on 13 June 1980. During this period the polarized emission appears decidedly two-sided with respect to the star. On 20 June 1980 the double structure has become quite extended, but a new component has appeared to the west of SS433. The changes in polarization can be understood if it is realized that the polarization vectors in Fig. 2 reflect the extended structure rather than the central radio source, in which the polarization averages out to very low levels. In the 7 December 1979 map the polarization angle rotates by nearly 90° from the inner side of the ejected material to the outer side indicating that the magnetic

Fig. 3 VLA 4,885-MHz linearly polarized intensity maps with contours at 10% levels starting with 90% and peak values in Jy per beam and lowest contour levels of: a, 4.6 mJy + 20% 8–9 September 1979; b, 7.6 mJy + 30% 16 September 1979; c, 4.3 mJy + 20% 7 December 1979; d, 2.6 mJy + 30% 7 March 1980; e, 4.3 mJy + 10% 5 April 1980; f, 3.2 mJy + 10% 20 June 1980. The grid of crosses corresponds to 2 arc s intervals.

fields are being rotated parallel to the flow of ejected material. This follows from the fact¹⁷ that in the transparent part of the spectrum the polarization of a synchrotron radiation source is perpendicular to the magnetic field, and for a uniform source with parallel field lines the fractional polarization is $(3\gamma+3)/(3\gamma+7)$, where the electron energy distribution is $KE^{-\gamma}$. As the typical spectral index of -0.6 corresponds to an electron energy distribution with $\gamma = 2.2$, fractional polarization of uniform field regions would be expected to be 0.71. Considering that the observed fractional polarization of the eastern features in the 7 December, 7 March, 5 April and 20 June maps is 8, 16, 16, and 16% respectively, there are clearly field inhomogeneities which would be expected from the complex geometries involved. In the 7 March map, where eastern and western jets have roughly the same flux levels, the inner polarization angles of the polarized double are roughly 0° (to the north) and are consistent with magnetic fields parallel to the inner flow regions. The strength of the outer feature to the east in Fig. 3d is too weak to consider the apparent rotation of the polarization angle to be real. However, the excellent signal-to-noise ratio of the 5 April polarization map shows that the polarized double source has both expanded and rotated its position angle to $\sim -25^\circ$. The signal-to-noise level of the eastern polarization feature suggests that the average magnetic field direction is perpendicular to the flow of radiating relativistic particles. In the polarized source map of 20 June the outermost features are the evolved versions of the double of the 7 March and 5 April maps with polarization angles rotated to -150° . The feature associated with newly appearing polarized flux in the 20 June map shows an ejected

flow at a position angle near 120° and a polarization angle of $\sim -60^\circ$, so again the magnetic field lines are nearly parallel to the flow.

The previous discussion unfortunately assumes negligible Faraday rotation between SS433 and the Earth. Before any definitive information can be derived from the position angle information, multi-frequency observations of SS433 and background radio sources must determine the line of sight contribution to Faraday rotation.

Figure 4 shows the total intensity maps, the polarization vectors superimposed on a few total intensity contours, and the polarized intensity maps for 5 April and 20 June 1980. The dominant 1,465-MHz emission is more extended and may have a steeper spectrum than the features dominating the 4,885-MHz maps. However, the poor resolution of the 20-cm maps precludes useful determination of the spectral indices for anything except the total source. The polarized intensity maps clearly show two strong peaks separated by 2.3 and 3.0 arc s on 5 April and 20 June respectively. Because of poorer resolution, all of the polarized emission of the western and eastern 'jets' is coalesced into a simple polarized double source expanding with an apparent separation speed of $0.2c$. Noting the location of the components of the separating double in Fig. 3, most of this motion is clearly due to the western component. The linear polarization vectors of the western and eastern components of the double are nearly perpendicular to each other. As the polarization angle for the dominant eastern and western components in the 4,885-MHz maps is essentially the same, the apparent rotation between western and eastern features in the

Fig. 4 VLA 1,465-MHz maps in total intensity, linear polarization vectors superimposed on selected total intensity contours, and linearly polarized intensity for 5 April 1980 in *a*, *b*, and *c*, respectively, and for 20 June 1980 in *d*, *e*, and *f*, respectively. The grid of crosses corresponds to 5 arc s intervals. Solid, dashed, and solid lines in *a* and *d* indicate position angles of 83° , 100° , and 117° respectively. In *a* the peak is at 0.63 Jy per beam while in *d* the peak is at 0.9 Jy per beam. In *a* and *d* the contours are at the 95, 80, 65, 50, 35, 20, 15, 10, 7, 5, 4, 3, 2, 1, 0.5, and -0.5% level, with *d* having lower contours at the $\pm 0.25\%$ level. In *b*, *c*, *e*, and *f* the peak polarization is 2.5 mJy per beam. In *c* and *f* the linearly polarized intensity contours are at the 90, 80, 70, 60, 50, 40, 30, 20, and -20% level. X, the location of the central radio source and optical image.

Fig. 5 Linearly polarized intensity maps for: *a*, 7 December 1979; *b*, 7 March 1980; *c*, 5 April 1980; *d*, 20 June 1980, showing the expansion at constant position angle of components A, B, and C to the east and A' and B' to the west. Position angles and components were determined from *d* and extrapolated inward for *c*, *b* and *a* to achieve the best match to the observed polarization structure.

1,465-MHz maps may be due to Faraday rotation produced by a plasma region around SS433.

The 15,035-MHz maps corresponding to the entries in Table 1 showed a dominant point source at the position of SS433, with only marginal signs of extended structure that were too close to the noise level to be considered significant.

Transverse motions of SS433 jet features

The most obvious indication of transverse motions in the extended structure of SS433 is the changing separation of the double source in the 1,465-MHz polarized maps. Portions of the S-shaped structures can be seen that would be expected from ejection of material at different time with different ejected position angles. This is most easily traceable in the later four maps in Figs 1 and 3. However, it is difficult to identify the locations of moving features. Fortunately, the low degree of polarization of the dominant central radio source and the relatively high degree of polarization of the extended structure means that the maps of linearly polarized intensity are a good means of evaluating the changes of extended structure with time. The maps made on 7 December, 7 March, 5 April and 20 June, 1980 are nearly ideal for tracing the evolution of identifiable features.

Figure 5 shows the linearly polarized emission for 7 December, 7 March, 5 April and 20 June 1980, with possible components identified as A, B, and C on the east side and A' and B' on the west side. The identification of features and the determination of position angles were made solely from the 20 June 1980 polarized map. The position angles for the A, BB', and C features are $88^\circ \pm 5^\circ$, $108^\circ \pm 5^\circ$, and $115^\circ \pm 10^\circ$ respectively. The vectors for the corresponding features in the 7 December, 5 April and 7 March maps were drawn preserving the 20 June position angles, but shortening the vectors to best achieve a match with the earlier polarized intensity maps. Table 2 shows the resulting angular distances (ϕ) for each

feature in each map. The uncertainties for the angular displacements in Table 2 are at least 0.1 arcs, and can be much higher when merged or nearly merged features are hard to locate. These angular displacements as a function of time are linear and their slopes—the proper motion of the features—are listed in Table 3. The average proper motion of the features is 0.0088 arc s per day.

As the features labelled A, B, and C have the most clearly identifiable motion, they can be used to identify when features moving at a proper motion of 0.0088 arc s per day would coincide with SS433. The results are JD - 2444000 = 139, 217, and 297, for A, BB', and C, respectively. From coincidence of probable origin time and position angle, the very weak features A and BB' in the 1980 linear polarization maps are almost certainly the remnant of the strong flaring that occurred between 7 August and 29 December 1979. Weakening of these features with time is not surprising as one of the main physical processes affecting the relativistic plasma in the SS433 jets is adiabatic expansion and energy loss.

The proper motion of the features is $(v/d) \sin \theta$, where v is the velocity of the feature, d is the source distance, and θ is the angle the feature is moving with respect to the observer. Using the ephemeris of Margon *et al.*¹⁵

$$\cos \theta = \pm[0.34 \cos 2\pi(\psi + \alpha) + 0.167] \quad (1)$$

where $\psi = (\text{JD} - 2433555.6 \text{ days})/164.0 \text{ days}$, $\alpha = 0.330$, the inclination angle of the system with respect to the sky is 80° and the precessing beam angle is 20° . Obtaining θ from the times of ejection gives for A, BB', and C 114° , 90° , and 109° . These angles yield a mean proper motion v/d of 0.0088 arc s per day. Because little or no slowing down of motion of the features is observed, their velocity is probably $0.26c$. This results in a distance to SS433 of 5.1 kpc.

It is difficult to explain the individual structure of the polarized emission of the ejected features. The A feature is decidedly one sided. The time of ejection of this feature corresponds to

Fig. 6 A schematic diagram of the kinematics of the SS433 system with some parameters as determined by Margon¹⁵, but with the 100° apparent mean position angle as determined from the radio data and identification of foreground/background location on the basis of the strength bias for eastern jets and the tendency for western polarized features and western jets to appear suddenly at distances of a few tenths of an arc s from the compact radio source. The location of the identifiable features A, B, and C are indicated along with the values of position angle and JD-2444000 at the time the observed transverse velocities would make them coincident with SS433.

individual flaring events in the Green Bank data¹². The time of the ejection of the BB' feature corresponds to a period of intense complex flaring such that multiple flares were ejected, perhaps along the two jets. The C feature is very weak and was ejected during a quiescent period.

The apparent motion of the BB' features indicates the same ejection angles on both sides of SS433, and thus ejection at the same epoch is likely. For features ejected simultaneously along the two beams, the proper motions of the two features must be corrected for time travel effects of special relativity. This effect allows the velocity of the jets to be distinguished unambiguously; the value of v/d will then give the distance to SS433. Unfortunately, the BB' ejection occurred at an angle θ close to 90°, thus negating any time travel effects between the BB' jets.

Optical jets and changing radio structure

The most important fact relating the optical jets of SS433 and the changing radio structures with angular size scales of 0.1–5 arc s is the coincidence of the $\pm 20^\circ$ cone angle for the apparent precession of the optical jets¹⁵ and the $100^\circ \pm 20^\circ$ region in which features are ejected with different position angles at different times. The other important data determined by the VLA maps, that should be related to the optical jets, are the fairly well-defined position angles of $88^\circ \pm 5^\circ$, $108^\circ \pm 5^\circ$, and $115^\circ \pm 15^\circ$ for the A, BB', and C features presumably ejected from the central regions of SS433 at JD-2444000 = 139, 217, and 297, respectively. Figure 6 indicates the location of these position angles on one of the possible geometries for the SS433 optical and radio jets. The association of the direction of rotation with the eastern jet is arbitrary. The western jet is put in the background because its features seem to appear suddenly at a distance of 2–3 light days from SS433. There is a strong bias for western jets to be weaker, and the observed Faraday rotation may indicate the presence of an absorbing region near the centre that affects the inner western jets more than the inner eastern jets. These choices, however, do not affect the important points concerning the correlation of radio and optical jets. Assuming the beam to precess in 164 days, we note from Fig. 6 that there is reasonable consistency between the initial position angles for the A, BB', and C features, their date of ejection, and their relation to a 164-day period. Based on this geometry, the radio data, and a 164-day period, the maximum red/blue shift point would be predicted to occur on JD2444170 and the maximum blue/red

shift point would be predicted to occur on JD2444250, with uncertainties of the order of 10–20 days. According to Margon¹⁵ the maximum red/blue shift and blue/red shift points were reached on JD2444157 and JD2444239. Considering the uncertainties in position angles and average transverse speeds, we conclude that the behaviour of the moving features in the VLA maps is consistent with an association of optical jets and radio jets in the inner regions where the flows producing the radio emitting particles originate. Without more detailed tracking of identifiable features, probably with maps made at weekly intervals, a better correlation of extended radio jets and optical jets cannot be established from VLA data alone.

Parameters of the SS433 radio source

When synchrotron radio sources have known distances, sizes, flux densities, and observable Faraday rotation, several parameters of the radio source can be estimated, albeit in a model-dependent manner. We now consider typical values of the core radio source and typical values of one of the extended jet structures.

Using a combination of surface integrals over appropriate portions of the total intensity and linearly polarized intensity maps, the flux densities and polarization characteristics as listed in Table 4 can be determined. In Table 4 the core flux density was determined from the sum of the clean components found before any extended components were subtracted. Thus the core sources in Table 4 are located on top of the plateau level of the extended structure. The extended flux density was determined by the difference between the total integrated flux and the core flux density. The fractional polarization was determined by the ratio of polarized flux density to extended flux density.

The best maps of total intensity and polarized intensity are for JD-2444000 = 306, 335, and 411. The fractional polarization for the extended structure for these maps is surprisingly close to a single value, 16%, for both 1,465 and 4,885 MHz. However, as this was a period with relatively little flaring, it is hard to assess the significance of this polarization compared with the more variable values made with earlier, poorer VLA maps, though the 8% polarization determined for the 7 December 1979 extended structure should be of comparable quality to later results.

Based on Table 4 we adopt the following values as typical for the SS433 central source and an extended lobe defined as one half of the extended structure: core source of 0.3 Jy at

4,885 MHz, with a size of 0.1 arc s (7.5×10^{15} cm assuming a distance of 5.1 kpc); and extended lobes of 0.05 Jy at 4,885 MHz, with a size scale of 1 arc s (3×10^{16} cm). One may calculate the magnetic field (B) and the relativistic electron energy (W_e) assuming equipartition of energy and magnetic fields^{18,19} which are $W_e = 1.5 \times 10^{42}$ erg and 3.1×10^{42} erg, $B = 0.0077$ and 0.0014 G, respectively, for the core source and extended lobe. These magnetic fields indicate synchrotron loss lifetimes of 10^9 – 10^{11} s. Therefore synchrotron losses cannot have a significant role in the evolution of the observed central and extended radio emission.

If we assume that the 90° polarization angle rotation between the two lobes of the 20 cm extended emission is due to Faraday rotation, we estimate a minimum value of electron concentration of 3 – 4 electrons cm^{-3} in regions with the product size and magnetic field as derived above.

The above approximations will have less effect on the results than the real changes of parameters due to known changes in the radio source, with the possible exception of an erroneous assumption that energy in relativistic protons can be neglected in the equipartition of energy argument used to determine the magnetic field.

Conclusions

In addition to highly variable radio emission coincident in position with the optical image of SS433, there are highly polarized radio jets with size scales 0.1 – 5 arc s. The extended structure that we describe as jets for convenience is confined to position angles of $100^\circ \pm 20^\circ$. Features occurring in this structure, particularly in maps of linearly polarized flux, can be traced over time periods of 200 days with a proper motion of

0.0088 arc s per day with constant position angle. Extrapolating back to a hypothetical time of ejection based on the observed proper motion, the position angles of the radio jet features are consistent with those expected from the optical jet locations at that time. If the velocity of the polarized features is the same as that of the optical emission lines, the source distance is 5.1 kpc.

The 100° position angle is very close to the position angle determined by the long baseline observations of Spencer²⁰ and the VLBI observations of Walker *et al.*²¹. It is also very close to the position angle for the bulges of the large scale W50 radio source surrounding²² SS433. The $100^\circ \pm 20^\circ$ cone of relativistic plasma ejection defined by the radio maps corresponds reasonably well to the position angles of the large scale X-ray emission seen by Seward *et al.*²³.

The estimated magnetic fields are 0.001 – 0.01 G, so synchrotron loss lifetimes are $>10^9$ s; therefore synchrotron losses are negligible compared with the adiabatic losses associated with the expansion of newly created relativistic plasma components.

The evolution of the radio structure of SS433 indicates that the basic model must be that of adiabatically expanding flows which are accelerating relativistic particles and generating magnetic fields while moving into a turbulent medium made up from previous ejections. Fitting a more complicated model to the variable structure of this source is left to a future analysis of these and more extensive VLA observations. The capability to map evolving structures that change with time scales of the order of a week is one of the unique advantages of studying SS433 with the VLA.

The VLA and the National Radio Astronomy Observatory are operated by Associated Universities, Incorporated, under contract with the NSF.

Structure of the hydrophobic protein crambin determined directly from the anomalous scattering of sulphur

Wayne A. Hendrickson

Laboratory for the Structure of Matter, Naval Research Laboratory 6030, Washington DC 20375, USA

Martha M. Teeter

Department of Chemistry, Boston University, 685 Commonwealth Avenue, Boston, Massachusetts 02215, USA

The highly ordered crystal structure of crambin has been solved at 1.5 Å resolution directly from the diffraction data of a native crystal at a wavelength remote from the sulphur absorption edge. The molecule has three disulphide bridges among its 46 amino acid residues, of which 46% are in helices and 17% are in a β -sheet. Crambin is shown to be an amphipathic protein, inasmuch as its six charged groups are segregated from hydrophobic surface elements. Phasing methods used here will also apply elsewhere.

BIJVOET'S observation¹ that anomalous scattering might aid in solving the phase problem has had many implications², including suggestions that departures from Friedel's law of

diffraction symmetry might suffice to determine directly the atomic structures of crystals containing heavy atoms^{3–5}. Anomalous-scattering methods have also been widely used

Table 1 Expected diffraction ratios for potential applications of resolved anomalous phasing

Molecule	N_P	N_A	$\langle \Delta F \rangle / \langle F_P \rangle$	$\langle F_A \rangle / \langle F_P \rangle$
Sulphur-rich proteins:				
Crambin	400	6S	1.4%	29%
Snake neurotoxin ³⁸	500	8S	1.5%	30%
Metalloproteins:				
Hi PIP ³⁹	700	4Fe/8S	5.3%	38%
Haemerythrin ¹⁹	1,000n	2nFe	3.0%*	17%*
Oligonucleotides:				
d(CpGpCpGpCpG) ⁴⁰	300	10P	1.6%	39%
Oligopeptides:				
Antamanide ⁴¹	100	10O	0.5%†	37%
Heavy-atom complexes:				
Myoglobin ⁴²	1,300	1Hg	4.5%	31%
Lysozyme ⁴³	1,100	1U	8.5%	39%

N_P is the approximate number of non-hydrogen atoms in the total molecule and N_A is the number of anomalous scatterers. (Omission of hydrogen atoms has a negligible effect on these calculations: $\langle F_P \rangle$ with hydrogens is $\sim 1.01\langle F_P \rangle$ without hydrogens.) The diffraction ratios are estimates for zero scattering angle. In the case of only one kind of anomalous scatterer these ratios are $\langle \Delta F \rangle / \langle F_P \rangle \approx 2^{1/2} (N_A^{1/2} \Delta f_A') / (N_P^{1/2} Z_{\text{eff}})$ and $\langle F_A \rangle / \langle F_P \rangle \approx (N_A^{1/2} Z_A') / (N_P^{1/2} Z_{\text{eff}})$ where Z_{eff} is the effective atomic number (~ 6.7 for non-hydrogen protein atoms) and Z_A' is $Z_A + \Delta f_A'$. F_P and F_A are structure-factor magnitudes of real contributions from the complete molecule and from anomalous scatterers only, respectively. Of course, the diffraction ratios will vary with scattering angle in the same way as the ratio of thermal and scattering factors for the anomalous scatterers to those of the other atoms. Except where noted all estimates are for CuK α radiation.

* At low resolution (for example, 5.5 Å) these values are enhanced by a factor of $2^{1/2}$ because the dimeric iron centre is then unresolved.

† Oxygen anomalous scattering is computed for CrK α radiation.

in protein crystallography⁶⁻¹¹, particularly as an adjunct to isomorphous-replacement phasing. We have now combined elements from these two traditions to solve the structure of crambin by exploiting the anomalous scattering of sulphur atoms at a single wavelength (1.54 Å of CuK α) far removed from the absorption edge of sulphur (5.02 Å).

Crambin is a small protein found in the embryonic tissue (cotyledons and hypocotyledons) of seeds from *Crambe abyssinica*, a relative of mustard and rape commonly known as Abyssinian cabbage. It is hydrophobic in that organic solvents are required to solubilize it. Van Etten *et al.*¹² characterized crambin after noticing that crystals formed during evaporation of an aqueous acetone extract of defatted seed meal. The remarkable crystalline order observed by Teeter for this protein (strong diffraction from spacings < 0.88 Å)¹³ correlates well with the unprecedented structural stability seen in solution by Llinás *et al.*¹⁴ using NMR spectroscopy. The function of crambin is not known. However, the recently completed chemical sequence¹⁵ reveals an unmistakable homology with the plant toxins purothionin¹⁶ and viscotoxin¹⁷. Crambin itself is not toxic when fed to rats¹⁸.

We set out to solve the crystal structure of crambin in view of its exceptional potential for providing detailed structural information and in the hope of shedding light on the function of this hydrophobic protein. When our efforts to prepare heavy-atom derivatives failed, we explored alternatives to isomorphous replacement for phase determination. Our experience in using anomalous scattering to locate the iron atoms in myohaemerythrin¹⁹ led us to contemplate an attempt based on the six sulphur atoms in crambin. An estimate of the magnitude of Bijvoet differences to be expected from crambin gave a value about half that found with myohaemerythrin and showed that sulphur scattering would account for 98% of the expected anomalous signal. The expected contribution of the sulphur partial structure to the protein diffraction pattern proved to be 29% ($\langle |F_S| \rangle / \langle |F_P| \rangle$), or 9% based on $|F|^2$ ratios. This

seemed to provide a plausible, albeit marginal, basis for the crystal structure analysis.

The amino acid sequence determination, begun to aid the crystallographic analysis, was about 65% complete when the first electron-density maps were obtained. Completion of the chemical sequencing was aided by, proceeded alongside and helped to verify the structure solution. The sequence, as reported elsewhere¹⁵, is shown in Fig. 1.

Diffraction measurements

The diffraction data were measured from a single crambin crystal, grown and mounted as described before¹³, in equilibrium with its mother liquor of 60% aqueous ethanol (v/v). This crystal had approximate dimensions of $0.2 \times 0.5 \times 0.4$ mm and gave unit cell parameters of $a = 40.96$, $b = 18.65$, $c = 22.52$ Å and $\beta = 90.77^\circ$. The space group is P2₁. X-ray reflections from Ni-filtered CuK α radiation were recorded at room temperature (22–24 °C) as peak-top ω step-scans on a Picker FACS-1 diffractometer that is controlled by the Vanderbilt program system²⁰. For spacings greater than 1.5 Å, both I_h and I_{-h} were measured. Care was taken to reduce systematic errors in the Bijvoet differences by successively collecting blocks of 25 reflections at $(\phi, \chi, 2\theta)$ and then their Friedel counterparts at $(\phi, \chi, -2\theta)$. After completing the 1.5 Å data set, $+2\theta$ measurements were continued in shells out to 0.95 Å spacings. At this point the crystal slipped and further measurements were abandoned.

The scans for the 1.5 Å data comprised 4-s counts at each of seven steps in 0.03° intervals in ω and at a single background point. Counts were corrected for possible coincidence losses. These data were then reduced to integrated intensities using the procedure of Hanson *et al.*²¹, which fits gaussian profiles over smoothly varying backgrounds. Standard corrections were made for Lorentz and polarization factors, absorption²² and scale²³. No correction was made for radiation damage. (A monitor reflection showed only 3% decay in I after 150 h exposure.) Residual systematic errors in the Bijvoet differences

$$\Delta F \equiv |F_h| - |F_{-h}| \quad (1)$$

were minimized by applying local scale factors²⁴ parameterized to be anisotropic. These scale factors, applied to $|F_{-h}|$, ranged from 0.97 to 1.01 and eliminated errors that swamp the signal. After scaling, r.m.s. (ΔF) is 2.3e for acentric data as compared with 1.4e for the centric ($h0l$) data where there is no signal. This symmetry estimate or error agrees well with that obtained from counting statistics and instrumental instability, r.m.s. ($\sigma_{\Delta F}$) = 1.6e. Thus, on average the anomalous-scattering signal is about 1.7e, $(\langle (\Delta F)^2 \rangle - \langle \sigma_{\Delta F}^2 \rangle)^{1/2}$, which is 2.1% of the r.m.s. (F).

This work concerns only the 1.5 Å data. The data from beyond 1.5 Å have not been processed.

Sulphur structure

The first task of the analysis, to locate the sulphur atoms, was accomplished by interpreting Patterson maps computed with coefficients of $(\Delta F)^2$ as suggested by Rossmann⁸. Peaks in such maps correspond to inter-atomic vectors between anomalous scatterers. However, because the coefficients involve small differences, the maps are very sensitive to erroneous measurements. Hence, differences with $|\Delta F| > 5$ r.m.s. (ΔF) were rejected as distribution outliers (four reflections) and the more

Fig. 2 A portion of the electron-density distribution for crambin at three stages in the analysis. Each frame encloses an area bounded by $0 < x < a/2$ and $0 < z < c$ and is a composite of the sections at $y = (19-21)b/40$. The adjacent, dense spherical features at the lower left are the sulphur atoms of Cys 16–Cys 26. The dense spheroid near the centre of each frame is S^* of Cys 32. S^* of Cys 4 lies just to the right of this and is centred above these sections. The ring of Pro 5 is seen in the plane of these sections. All the maps are at 1.5 Å resolution. Frame *a* is part of the initial Fourier synthesis from which the structure was interpreted. Coefficients of $m(\frac{1}{2}(|F_h| + |F_{-h}|) \exp(i\phi))$ were used with figures of merit and phases determined as follows. Bimodal anomalous distributions for which the partial-structure choice-probability²⁹ exceeded 0.7 were given the phase of the chosen mode and weighted by the intrinsic figure of merit²⁹ (30% of the 5,660 reflections). Phasing for relatively sharp unimodal distributions, $m_{\text{ano}} > 0.4$ and $m_{\text{ano}} > m_{\text{combine}}$, was kept at ϕ_{ano} and m_{ano} (8%). For the remaining cases, the centroid phases and weights, m_{combine} , were determined from multiplicatively combined distributions³⁰. These included the centric zonals (11%) and error rejects (2%), for which there was no anomalous phasing, as well as the other general reflections (48%). Partial structure probabilities were computed with $Q = 2$. Overall, $\bar{m} = 0.55$. Frame *b* is from the first $(2F_{\text{obs}} - F_{\text{calc}})$, ϕ_{calc} map after direct refinement of the initial model to an agreement factor of $R = 0.322$. Frame *c* is the latest $(2F_{\text{obs}} - F_{\text{calc}})$, ϕ_{calc} map from the model at $R = 0.104$.

error-prone weak data with $|F_h|$ or $|F_{-h}| < 5\sigma_F$ were also excluded (127 reflections). Small Bijvoet differences, $|\Delta F| < 1.2\sigma_{\Delta F}$, were also left out (3,038 reflections) but this had little impact on the maps.

These anomalous-difference Patterson maps were remarkably clean. The first map was computed at 3 Å resolution and could readily be interpreted as arising from three sites that correspond to unresolved disulphide units. When the data to 1.5 Å spacings were also included, the disulphide Patterson peaks became resolved into clusters of peaks from which the six-atom sulphur structure was deduced.

It is easy to show⁹⁻¹¹ that for a structure containing relatively weak anomalous scatterers all of one kind, for example, sulphur in crambin,

$$\Delta F \approx -2\delta \sin(\psi - \phi) \quad (2)$$

Here, $F \exp(i\phi)$, where $F \approx \frac{1}{2}(|F_h| + |F_{-h}|)$, is a structure factor from the real parts of the scattering and $\delta \exp(i\psi)$ is calculated from the anomalous scatterers when given the imaginary components, $\Delta f''$, for scattering factors. This relationship, which also explains the effectiveness of the $(\Delta F)^2$ Patterson synthesis, provides a basis for refining the structure of anomalous scatterers and ultimately for phasing the whole structure. As $|\Delta F|$ becomes large the sine factor must approach ± 1 so that $|\Delta F| \approx 2\delta$. Thus, atomic parameters of anomalous scatterers can be refined against $|\Delta F|$ values if only the largest differences are included. This was first done for myohaemerythrin to give a quite precise Fe–Fe distance¹⁹.

Refinement of the crambin sulphur structure was against a data set restricted, by rejection criteria described above, to the 1,910 strongest from among a total of 5,017 Bijvoet differences. The value of $\Delta f''$ for sulphur was taken to be 0.557 (ref. 25). The refinement reduced R to 0.33. Disulphide distances, unrestrained, in the resulting structure were in good agreement with expectation: $d = 2.00, 2.02$ and 2.04 Å with $\sigma_d = 0.06$ Å.

Phase determination from partial-structure resolved anomalous scattering

Phase information from anomalous scattering at a single wavelength, like that from a single isomorphous replacement

experiment, is intrinsically ambiguous. Given an observed ΔF and the values of δ and ψ calculated from refined atomic parameters, equation (2) can be solved for the desired phase, ϕ , for the reflection. However, the possible solutions at $\phi = \psi + \pi/2 \pm \theta$, $\theta = \cos^{-1}(\Delta F/2\delta)$, are equally likely. Moreover, due to the substantial errors in ΔF , other phases may also be plausible or, quite possibly, a formal solution will be precluded. This ambiguity and imprecision in phases can be taken into account by using a probability treatment of the kind introduced by Blow and Crick²⁶. We have used an error model¹¹ whereby the probability distribution, $P_{\text{ano}}(\phi)$, for phase information from anomalous scattering is

$$P_{\text{ano}}(\phi) = N \exp \{ -[\Delta F + 2\delta \sin(\psi - \phi)]^2 / 2E^2 \} \quad (3)$$

The standard error, $E = (\sigma_{\Delta F}^2 + E_0^2)^{1/2}$, is composed of the error

Fig. 3 A schematic drawing of the backbone of crambin. This representation of crambin was drawn by Jane Richardson to be faithful to computer drawings of the skeleton. Arrows depict β -strands. The disulphides are drawn as 'lightning flashes'. The reader looks down along *b*; *a** runs from left to right and *c* runs from page bottom to page top.

in ΔF and a residual lack-of-closure error, E_0 (ref. 27). N is a normalization factor.

The phase ambiguities, $\pm\theta$, must be resolved for the anomalous scattering to be of use. If the anomalous scatterers are sufficiently heavy, then phases for the total structure, ϕ , will tend to be close to those for the heavy-atom structure, ψ . One can then simply take the anomalous alternative that is nearer to the heavy-atom phase³⁻⁵. However, this process is often not valid if, as in the case of crambin, the partial structure of anomalous scatterers is not a dominating influence. Thus, we have used a probability treatment where the distribution, $P_{\text{par}}(\phi)$, for phase information for the sulphur partial structure is based on that given by Sim²⁸

$$P_{\text{par}}(\phi) = N' \exp \{2Q|F_p||F_s| \cos(\psi - \phi) / \langle F_U^2 \rangle\} \quad (4)$$

Here, $\langle F_U^2 \rangle$ is the expected value of the scattering contribution from the unknown part of the structure; $|F_p|$ and $|F_s|$ are the structure factor moduli observed for the protein and calculated from the sulphur structure, respectively; Q is an arbitrary sharpening factor.

These probability representations were used to combine the phase information from anomalous scattering with that from the

sulphur partial structure and also to compute figures-of-merit, m , for weighting the Fourier synthesis. After some experimentation we settled on a scheme for probabilistic choices²⁹. A choice was made if the partial-structure probabilities (equation (4)) discriminated well between alternative maxima in the anomalous scattering distribution (equation (2)). Sharp unimodal distributions were used directly. Otherwise, $P_{\text{ano}}(\phi)$ and $P_{\text{par}}(\phi)$ were multiplicatively combined³⁰.

There remains one further ambiguity. The sulphur structure deduced from Patterson maps could equally well be of either hand. Nothing in the anomalous-scattering and partial-structure information decides directly between enantiomers, but resulting phases will only be sensible when based on the correct choice. Independent information is required. Chemical reasonableness in a Fourier synthesis seemed to favour one sulphur enantiomer. This choice was corroborated by Sayre phase refinements³¹ on both hands. (This 'refinement' reduced the residuals to $R = 0.23$, but it actually degraded the map.)

Interpretation of the electron-density map

A part of the Fourier synthesis in the proper hand is shown in Fig. 2a. The most striking density in this map comes from the

Fig. 4 Stereo drawings of the crambin atomic structures. Bonds along the main-chain backbone are enhanced. The conformational and compositional heterogeneity at positions 7, 22 and 25 is included. Residue numbers are given near the C^α positions of Thr 1, Gly 20 and Gly 42 in each of the views. *a*, View, as in Fig. 3, through the thinnest dimension. *b*, View along *c* with *a** running from left to right. This is approximately along the helical stem and perpendicular to the β -sheet (towards the back at the right). *c*, View into *a** with *c* running from left to right. This is approximately perpendicular to the helix axes as seen from the β -arm side. These stick figures and the surface diagrams (Figs 5 and 6) were all drawn using the program PLT1 written by G. J. Quigley.

known sulphur atoms, but other rather atomistic features are also evident. Yet, the map has quite an uneven quality. In an initial survey we correctly identified four side groups (later to be Pro 5, Tyr 44, Phe 13 and Asn 14), but peptide linkages to adjacent residues were not readily apparent even with knowledge of a tentative sequence for the first 33 residues. However, it did prove possible to fit the prominent proline ring (Fig. 2) and two sulphur atoms with a model of the unique -Cys 3-Cys 4-Pro 5-peptide, albeit through some weak density.

The seeming reasonableness of these parts of the map encouraged us to attempt a complete interpretation. The fitting was made without recourse to graphics sophistication. Rather, we simply followed density features contoured on paper ($5 \text{ mm } \text{\AA}^{-1}$), proceeding outward from the disulphide bridges while bearing in mind standard stereochemical rules. Putative atomic positions were marked on the sheets. Several polypeptide segments evolved and eventually joined up. The last connections, residues 18-22 and 37-41, were rather tenuous but they did complete the chain. It was a heartening verification of the model when helices were finally recognized. Atomic coordinates were read off the map with the aid of a gridwork overlay.

Model refinement and revision

The initial model included 338 non-hydrogen atoms from 45 amino acid residues and 18 water molecules. This model fitted the diffraction pattern with a reliability index $R = \Sigma |F_{\text{obs}} - F_{\text{calc}}| / \Sigma F_{\text{obs}}$ of 0.43 for the data from spacings between 5 and $1.5 \text{ \AA}$. Twelve cycles of stereochemically restrained refinement³² reduced R to 0.32 while imposing moderately good geometry as typified by the r.m.s. deviation from bond ideality of $0.04 \text{ \AA}$. Individual isotropic thermal parameters were varied but with tight restraints³³.

Several iterations of map interpretation, model revision and continued refinement followed. Inspection of the first ($2F_o - F_c$) synthesis (Fig. 2b) and the corresponding ($F - F_c$) difference map revealed a number of misplaced atoms, particularly in segments 18-22 and 37-41. A model with the polypeptide backbone revised in these segments then refined to an R of 0.27. Repair of side chains (40% were wrongly identified initially in the unsequenced C-terminal portion), addition of water mole-

Fig. 6 Hydrophobic surface of crambin. The radii used here are the same as those in Fig. 5. Atoms designated as hydrophobic here only include the side-chain carbon atoms of Ala, Val, Leu, Ile, Phe and Tyr residues, C^β and C^γ of Pro and C^γ of Thr. *a*, View looking into the hydrophilic inner bend, as in Figs 4b and 5b, showing hydrophobic residues that line the left-wall and underside surfaces. *b*, View looking into the left-wall surface along a^* with c running from right to left. Note that the polar side chain of Asn 12 is partially covered by the hydrophobic cloak of an ethanol molecule.

cules to a total of 39, and further refinement brought R down to 0.17. It then became apparent that some of the supposed water sites actually constituted a 46th residue.

Finally, special attention was paid to solvent regions and to side-group assignments. Another ~40 solvent molecules were located on inclusion of the $5\text{--}10 \text{ \AA}$ shell of data and, after release of thermal restraints, residue identifications were completed down to the distinctions between N and O needed to assign Asp 43 and Asn 46. This took R to 0.12. Side-group assignments were confirmed at this point by the completed chemical sequence analysis. A model was then devised to account for the conformational and compositional heterogeneity at three residue positions. Isotropic refinement of this model (414 atomic sites including 72 water and 4 ethanol molecules) against all 5,638 data in the $10\text{--}1.5 \text{ \AA}$ shell gave $R = 0.114$ with bond ideality of $0.018 \text{ \AA}$. Anisotropic refinement with restraints³³ such that the r.m.s. bond-distance fluctuation was kept to $0.05 \text{ \AA}$ gave $R = 0.104$ (see Fig. 2c). The resulting coordinates will be deposited in the Protein Data Bank.

Molecular conformation

Crambin has the shape of the Greek capital letter gamma (Γ) when viewed as in Fig. 3. (We describe crambin in terms of a model so oriented lying on a table before the reader.) The stem of the Γ is an antiparallel pair of helices and the cross-arm consists of two antiparallel β -strands, an irregular strand and a classic β -turn. The backbone skeleton of crambin (Fig. 3) gives an impression that the relatively thin β -arm is only tenuously connected to the helical stem. This belies the exceptional degree of rigidity in crambin¹⁴. In fact, side chains fill the axillary juncture, or inner bend, between the stem and the arm with numerous stabilizing salt bridges, hydrogen bonds and other contacts (Figs 4, 5). The disulphide bridges further fix the internal structure of the sub-domains.

The local conformational parameters of crambin fit remarkably well with accepted principles of secondary structure³⁴. Backbone conformation angles are all within allowed regions of the (ϕ, ψ) plot, although the conformations at three glycine residues (20, 31 and 37) would be disallowed for any other residue. All the peptide bonds are *trans*. The present restrained model has an r.m.s. deviation of 3.8° from peptide planarity. Only the ω angles following residues 29-31 and 44-45 deviate

Fig. 5 Ionic surface of crambin. These surface representations of crambin have the following Van der Waals radii: C, $1.7 \text{ \AA}$; N, $1.4 \text{ \AA}$; O, $1.4 \text{ \AA}$ and S, $2.1 \text{ \AA}$. No hydrogen atoms are included. Positively charged groups of atoms are shaded with dotted circles and negatively charged groups are shaded with solid circles. *a*, View of the molecule as in Fig. 3 and in Fig. 4a. *b*, View looking into the inner bend of the Γ from along the helix axes as in Fig. 4b. *c*, View looking into the inner bend perpendicular to the helix axes as in Fig. 4c.

from planarity by more than 5°, the greatest deviation being 11°. Side-chain conformation angles also lie close to 'ideal' values. The 43 χ angles that are expected to be staggered have an r.m.s. deviation of only 9.5°. Two of the three aromatic residues are within 4° of the expected transverse conformation at χ_2 , but Tyr 29 has $\chi_2 = 55^\circ$. The disulphide torsion angles, which are also expected to favour $\pm 90^\circ$, are -79° (3-40), 106° (4-32) and -86° (16-26).

Residues 1-4 and 32-35 produce β -strands linked by four hydrogen bonds. The (ϕ, ψ) angles in these segments average $(-121^\circ, 148^\circ)$. This two-stranded β -sheet has the usual left-handed twist when viewed perpendicular to the strands. Residues in extended conformations at 39-41 form a third strand that is not in the β -sheet.

Residues 7-19 and 23-30 are in helices. The first 10 residues in the upper helix have (ϕ, ψ) angles that average $(-62^\circ, 42^\circ)$ and only vary by $\sigma_\phi = \sigma_\psi = 4^\circ$. A disruptive proline at the C-terminus of this helix is accommodated by 3_{10} -helix conformations at positions 17 and 19. The last residue in the lower helix, Thr 30, has a distorted 3_{10} -like conformation, but otherwise this helix is also α -helical. Its (ϕ, ψ) angles average $(-65^\circ, 37^\circ)$ but it is somewhat less regular than the upper α -helix, $\sigma_\phi = 6^\circ$ and $\sigma_\psi = 8^\circ$. The angle between helix axes is 139° .

Residues 5-6, 20-22, 31, 36-38 and 42-43 produce the five turns in the crambin tertiary fold. Four of these segments contain or are immediately preceded by proline residues and four include glycines. The first four turns are relatively gradual and each is negotiated in a characteristic way. However, the last turn is a sharp reversal, with a carbonyl-41 to amide-44 hydrogen bond. It is a type I β -turn, the most common kind, and has (ϕ, ψ) angles of $(-62^\circ, -23^\circ)_{42} \rightarrow (-90^\circ, -2^\circ)_{43}$.

Conformational heterogeneity exists at Ile 7 and Ile 25 where C δ^1 atoms take either of two staggered possibilities. Compositional heterogeneity also exists at positions 22 and 25. Refinement parameters suggest that residue 22 is ~60:40 Pro/Ser and that residue 25 is ~60:40 Ile/Leu. The heterogeneity at residue 22 apparently causes a disorder in Tyr 29; the refined position of its O ^{n} makes an impossibly short contact of 2.6 Å with C δ of Pro 22 on a screw-related molecule.

Amphipathic protein surface

The surface of crambin has an amphipathic character. The six charged groups (1 NH $^+$, 10 Arg $^+$, 17 Arg $^+$, 23 Glu $^-$, 43 Asp $^-$ and 46 COO $^-$) as well as several other hydrophilic side chains are clearly segregated from what otherwise is largely a hydrophobic molecular surface. The surface of crambin can be understood as comprising three components. The face of the inner bend between the helical stem and the β -arm is a sloping surface that is almost entirely hydrophilic (Fig. 5). The other two surface elements, namely the left wall of the helical stem and the underside of the molecule, are primarily hydrophobic (Fig. 6). The left-wall surface curves gently around the outer bend while the underside surface is relatively flat.

All but one of the charged groups are clustered on the face of the inner bend. Six of the 13 other polar side chains also line or rim this surface. These groups are highly interconnected. For example, the guanidinium group of Arg 10 makes a salt bridge to the terminal carboxyl oxygens of Asn 46, forms hydrogen bonds to the hydroxyl and carbonyl oxygens of Thr 2, and interacts with the amide oxygen of Asn 14 through a tightly bound water molecule. Bridging water molecules also link the carboxyl group of Glu 23 to the terminal amino group of Thr 1

and the guanidinium group of Arg 17. In the crystal this chain of alternating charges continues to the carboxyl group of Asp 43 in a molecule related by lattice translation.

Unlike the inner-bend surface, or the surfaces of water-soluble proteins in general, the remainder of crambin is interspersed with hydrophobic groups. The left-wall surface includes eight fully exposed leucine, isoleucine, valine, proline and tyrosine side groups and the underside surface contains seven such exposed groups. There are also exposed polar side groups on these surfaces, but several of these are hydrogen-bonded back to the main chain.

The most extensive packing contacts in the crystal involve Van der Waals interactions between juxtaposed left-wall surfaces. There are only four direct intermolecular hydrogen bonds in the asymmetric unit, all other lattice interactions being mediated through water molecules. Although water is excluded from the left-wall contacts, it surrounds the remaining available surface. Most of the water molecules are associated with the hydrophilic inner bend, but elsewhere a number are actually in contact with hydrophobic side chains. Surprisingly little of the ethanol is bound detectably. Only four ethanol sites with a total occupancy of 2.3 have been located, whereas the 72 identified water sites have occupancies totalling 52.7. If the solvent space (34% of the crystal) had the composition of the mother liquor (60% ethanol), we would expect 18 ethanol and 39 water molecules per asymmetric unit.

It is likely that the amphipathic character of the crambin surface has significance for the physiological activity of the molecule. Unfortunately, the biological role of crambin is unknown.

Prospective applications

It might seem that anomalous-scattering methods as used here would apply solely to special, highly ordered structures like crambin. However, estimates of phasing power suggest that these methods may have broad applicability. Expected diffraction ratios related to anomalous-scattering and partial-structure strengths have been calculated for various crystals of known structure (Table 1). Many of these problems give ratios that compare favourably with those for crambin and probably they too could have been solved from partial-structure resolved anomalous scattering. This is true both for structures with native anomalous scatterers and for heavy-atom complexes.

Although Bijvoet differences may be small, with appropriate experimental design most systematic errors can be eliminated. Moreover, as only a single crystalline species is used, derivatives need not be isomorphous. Also, phasing power carries on well to high resolution, although high resolution is not a requirement. We have recently solved the structure of a trimeric haemerythrin at 5.5 Å resolution using Fe-resolved anomalous phasing followed by molecular averaging for phase refinement (J. L. Smith and W. A. H., unpublished). The possibility of performing multi-wavelength experiments at synchrotrons³⁵⁻³⁷ enhances the promise for anomalous-scattering applications.

The crystal structure of crambin should be a good model for exploring protein conformations, fluctuations and solvent interactions in extraordinary detail. Further diffraction studies and toxicity analyses are in progress.

We thank Jane Richardson for her drawings, Gary Quigley for his plotting programs, and Janet Smith and Jerome Karle for discussions. This work was supported in part by NSF grant PCM80-03929 to M.M.T.

Regulation of adenovirus-2 gene expression at the level of transcriptional termination and RNA processing

Joseph R. Nevins & Michael C. Wilson*

The Rockefeller University, New York, New York 10021, USA

The major late adenovirus-2 transcription unit is active early in infection at a rate equal to that of the other early transcription units. However, transcripts seem to terminate early in infection near map position 60–70 in contrast to late in infection, when termination occurs at map position 99. RNA processing, both poly(A) site selection and splicing, results in the production of a single L1 mRNA during early infection. All these processes are in contrast to those occurring late in infection, indicating that the events of transcriptional termination, poly(A) site selection and splicing can change depending on the conditions of the cell and therefore can participate in the regulation of gene expression.

THE mechanisms that control gene expression in eukaryotic cells are clearly of great importance, but these processes are only poorly understood. The ultimate result of gene regulation, the concentration of functional mRNA in the cytoplasm, could be brought about through the control of transcription, RNA processing and transport, mRNA cytoplasmic stability, or translatability of the mature mRNA. Our aim has been to determine at which of these steps regulation of adenovirus gene expression occurs.

Of the eight known transcription units on the adenovirus chromosome (see Fig. 1), five function primarily early in infection (before DNA replication)^{1–3} while at least two, which are responsible for mRNAs coding for structural proteins IX (refs 3, 4) and IVa2 (ref. 5), become active at intermediate times.

* Present address: Scripps Clinic and Research Foundation, Department of Cellular and Developmental Immunology, La Jolla, California 92037, USA.

The major viral transcription unit active late in infection is responsible for the production of mRNAs coding for most of the structural polypeptides of the virus^{1,6–8}. The initiation site and probably the promoter for this transcription unit, located at map coordinate 16.45 (ref. 9), directs transcription in the rightward direction with termination very near the end of the genome¹⁰. The mRNAs produced from the late transcription unit are arranged into five families of RNAs, L1–L5, the RNAs within a family being 3' co-terminal^{11–14}. Expression of the late transcription unit involves selection of a particular poly(A) site (3' end) among the five possible sites followed by splicing of the tripartite leader sequences to produce one of the mRNAs of the given mRNA family¹⁵.

Although it has long been believed that the expression of the major late transcription unit occurs only after DNA replication, we now show that the late transcription unit is in fact transcribed early in infection but that it is regulated at the point of transcriptional termination in such a way that early in infection only

Fig. 1 *a*, Genomic map locations of the early, intermediate (IVa2 and IX) and late adenovirus transcription units. *b*, Map depicting the genomic positions of the early mRNAs of regions E2, E3 and E4 and the mRNAs of the late 3'-co-terminal families L1, L2 and L3 deriving from the late transcription unit^{11,12,14,17,32}.

Fig. 2 Sensitivity of early adenovirus RNA synthesis to UV-ray irradiation. *a, b*, At 5 h post-infection, HeLa cells which had been maintained in the presence of $25 \mu\text{g ml}^{-1}$ of cytosine arabinoside were concentrated to 2×10^6 cells per ml. Samples of 2×10^7 cells were UV-ray irradiated for the indicated times¹⁰ and 20 min later were labelled for 5 min with ^3H -uridine. The nuclear RNA was purified and hybridized to filters containing the various DNA fragments prepared as follows: adenovirus-2 DNA restriction fragments of coordinates 0–4.4 (*Hpa* E), 62.9–65.6 (*Bal* K), 70.7–75.9 (*Eco* F), 83.4–89.7 (*Eco* E) and 89.7–100 (*Eco* C) were inserted into the *Pst* site of pBR322 and propagated in *E. coli* HB101. Clones of the *Hind*III I and D fragments were gifts of Dr M. Mathews. A clone of the *Sma* F fragment was a gift of Dr R. Roeder. All procedures for growth of bacteria and handling of recombinant DNAs were in accordance with the NIH Guidelines for Recombinant DNA Research. Plasmid DNAs were purified according to the procedure of Clewell and Hsien³³. Other DNA fragments were prepared by digestion of viral DNA³⁴. In each case, the RNAs were partially broken with alkali before hybridization³⁵. Therefore, any problem arising from possible symmetrical transcription would be eliminated due to denaturation of RNA–RNA duplexes. Such duplexes would then be unlikely to re-anneal due to the vast DNA excess in the hybridizations. Hybridized c.p.m. in the control samples (no UV) were: 454 (0–4.4); 879 (11.6–18.2); 3,330 (18.8–29.1); 1,582 (31.5–37.3); 1,776 (41.0–50.1); 549 (62.9–65.6); 1,534 (70.7–75.9); 351 (83.4–89.7); 747 (89.7–100). *c*, The slopes (*K* value) of the UV inactivation curves were calculated and plotted as a function of genomic map position of the DNA fragment. $K = (\ln R_0/R)/d$ where R_0 = rate of RNA synthesis in the control and R = rates of RNA synthesis at dose d (ref. 19).

the first half is transcribed. We also find that RNA processing, both 3'-end selection (poly(A) site) and 5'-end selection (splicing), is different early and late in infection, which suggests that the regulation of gene expression can in fact be mediated at least in part through RNA processing.

Early transcription of late sequences

Recent reports that sequences corresponding to late RNA can be detected during early infection^{16–18} have thrown little light on their relative frequency or the extent of transcription. Accordingly, we have used the technique of UV-ray irradiation transcription mapping to investigate the early transcription of various regions of the adenovirus-2 genome. The principle is that the transcriptional effectiveness of a sequence in an irradiated DNA template decreases exponentially with increasing distance from the promoter¹⁹. The transcriptional activity of the various parts of the genome can be measured by hybridizing the RNA labelled during 5-min pulses of ^3H -uridine with DNA fragments corresponding to defined sections of the genome.

HeLa cells early in infection (5 h post-infection) in the presence of cytosine arabinoside to prevent viral DNA replication) were treated with various doses of UV rays and then with ^3H -uridine. The labelled nuclear RNA was hybridized to a variety of DNA fragments from the adenovirus genome (Fig. 2*a, b*). Figure 2*a* presents the results for sequences between 11 and 50 map units and Fig. 2*b* those for sequences to the right of 62 map units. The data obtained were plotted to compare the sensitivity to UV-ray inactivation of the various sequences (the slopes of the UV-ray inactivation curves) as a function of their position in the genome (Fig. 2*c*). Region E2 is represented by the DNA fragments at 62.6–65.9 map units, and 70.7–75.9 map

Table 1 Extent of rightward transcription during early infection

Expt	DNA	Map coordinates	Hybridized c.p.m.	c.p.m. per kilobases of hybrid
1*	<i>Sma</i> I	36.7–40.5	883	645
	<i>Kpn</i> I	39.6–42.7	495	442
	<i>Kpn</i> H	42.7–47.4	1,555	920
	<i>Sma</i> H	52.6–56.9	1,120	723
2*	<i>Sma</i> B/ <i>Bam</i> B	18.8–29.1	982	265
	<i>Sma</i> A/ <i>Eco</i> A (rightward)	56.9–58.5	149	266
	<i>Sma</i> A/ <i>Eco</i> A (leftward)	56.9–58.5	182	325
	<i>Eco</i> F	70.7–75.9	850	538
3†	<i>Sma</i> I	36.7–40.5	405	337
	<i>Sma</i> H	52.6–56.9	553	357
	<i>Bal</i> K (rightward)	62.9–65.6	69	138
	<i>Bal</i> K (leftward)	62.9–65.6	169	338
	<i>Eco</i> F	70.7–75.9	489	309

At the appropriate time post-infection cells were concentrated to 1×10^7 cells per ml in fresh, warm minimal essential medium. ^3H -uridine was added at $200 \mu\text{Ci ml}^{-1}$ and then incorporation of label was halted by pouring the cells on to crushed frozen phosphate-buffered saline. Nuclear RNAs were then extracted as described previously^{29–31}. The nuclear RNA was hybridized to the various DNA fragments immobilized on nitrocellulose filters¹². The source of the DNAs were described in Fig. 2 legend. To determine relative rates of transcription, each value for hybridized c.p.m. was corrected for the size of the hybrid (the size of the DNA fragment). One map unit was assumed to represent 350 nucleotides. The exception is the *Bal* K fragment, which represents 2.7 map units or 0.97 kilobases. The DNA used in this work was a clone of *Bal* K in which only 0.5 kilobases of the fragment was obtained in the cloned plasmid.

* At 5 h post-infection, a sample of 2×10^7 cells which had been maintained in cytosine arabinoside ($25 \mu\text{g ml}^{-1}$) was concentrated to 1×10^7 cells per ml and labelled with ^3H -uridine ($200 \mu\text{Ci ml}^{-1}$) for 5 min. Nuclear RNA was prepared and hybridized to the various DNA fragments.

† Same as in *a* except that cells were labelled at 3.5 h post-infection.

Fig. 3 Kinetics of accumulation of ^3H -uridine into cytoplasmic poly(A) $^+$ RNA hybridizing to early region 2 DNA (left panel) and to L1, L2 and L3 DNAs (right panel). At 5 h post-infection, cells which had been maintained in the presence of $25 \mu\text{g ml}^{-1}$ of cycloheximide were concentrated to 4×10^6 cells per ml. ^3H -uridine was added ($200 \mu\text{Ci ml}^{-1}$) and samples of 5×10^7 cells were taken at the indicated times. Cytoplasmic RNA was purified from each sample²⁹⁻³¹, selected on poly(U)-Sephacrose³⁶ and hybridized to the appropriate DNA fragments immobilized on nitrocellulose filters¹². E2 (*Bal K*, 62.9–65.6), L1 (*HindIII I*, 31.5–37.3), L2 (*HindIII D*, 41.0–50.1), L3 (*Sma H*, 52.6–56.9).

units with the curve originating at the region of greatest resistance to UV-ray irradiation, the promoter at coordinate 75. Transcription of the other regions of the genome containing early transcription units (regions 1A, 3 and 4) was also found to be very resistant to UV-ray inactivation as expected considering the proximity of these particular sequences to their promoters. The transcription detected between map positions 16 and 50 apparently derives from the region of map position 16. Note that the slope of this curve is opposite to that of the early region 2 curve, indicating transcription proceeding in the opposite direction. These results therefore indicate that the region between 16 and 50 map units is transcribed as a single unit, reading in the rightward direction and originating near map position 16. Fingerprint analysis of RNA made early in infection and specific to the 16–18 region indicated that the major late promoter was indeed active²⁰. Furthermore, the RNA detected by electron microscopy during early infection both in the cytoplasm¹⁶ and in the nucleus¹⁷ possessed a 5' terminus which mapped to genome coordinate 16. It is therefore likely that the same promoter at map position 16.45 which directs transcription during late infection is responsible for the synthesis of RNA which we have detected during early infection. In addition, comparison of the hybridized c.p.m. in the control samples (no UV) of Fig. 2 for the various regions of the genome indicates that the late sequences are transcribed at a rate equal to that of any of the early transcription units, a result also obtained by Shaw and Ziff²⁰.

As shown in the experiment in Fig. 2, transcription in the rightward direction originating at the late promoter at map position 16 does not extend to map position 70 and beyond. For example, transcription of the 83.4–89.7 region originating at map unit 16.45 would have a UV target size of 25 kilobases,

yielding a K value in Fig. 2 of ~ 21 . Rather, the value of 0.6 which was obtained suggests a very small UV target size, fully consistent with the hypothesis that all this transcription is derived from the early region 3 promoter. This argument can be made because in this experiment the rate of transcription of the late sequences between map coordinates 18 and 50 was approximately four times that of the 83.4–89.7 region. Thus, even a very small amount of readthrough from the late region into the region of 83.4–89.7 would have greatly increased the UV-ray sensitivity. In addition, transcription in the rightward direction of the sequences between 70.7 and 75.9 map units originating at or near the promoter at coordinate 16 would have a UV target size of 20 kilobases, yielding a K value in Fig. 2 of ~ 16 ; thus, as transcription of the late region was proceeding at a rate equal to that of early region 2 in this particular experiment, transcription of 70.7–75.9 DNA sequences in both the rightward and leftward directions would yield an average K value of close to 8, which clearly was not the case. This suggests that transcription in the rightward direction terminated somewhere between 50.1 and 70.7 map units before reaching the 70–75 region. To define this site more accurately, pulse-labelled nuclear RNA was hybridized to separated strands of the *Eco A/Sma A* fragment (map coordinates 56.9–58.5) and the *Bal K* fragment (map coordinates 62.9–65.6, Table 1). The leftward-reading strand of each fragment detects early region 2 transcription²¹; transcription of each of these was approximately equimolar to that of the *Eco F* fragment (70.7–75.9). The rightward-reading strand of the *Sma A/Eco A* fragment also hybridized pulse-labelled nuclear RNA; the hybridized radioactivity, when compared with that for fragments to the left, indicated transcription to be equimolar from 16.45 through the 56.9–58.5 region. In a separate experiment, the rightward-reading strand of the *Bal K* fragment also hybridized labelled nuclear RNA but only about 40% of that which hybridized to the leftward-reading strand of the *Bal K* fragment. Because transcription of the *Sma I* (36.7–40.5), *Sma H* (52.6–56.9), *Eco F* (70.7–75.9) and leftward *Bal K* (62.9–65.6) fragments all appeared to be equimolar, it is possible that transcription in the rightward direction terminates

Fig. 4 Kinetics of accumulation of ^3H -uridine into nuclear poly(A) $^+$ RNA hybridizing to early region 2 DNA (left panel) and to L1, L2 and L3 DNAs (right panel). Nuclear RNA was prepared from the experiment described in Fig. 3 legend, selected on poly(U)-Sephacrose and hybridized to the same DNA probes described in Fig. 3 legend. The cytoplasmic RNA accumulation curves (---) from Fig. 3 have been plotted for comparison.

Table 2 Rates of accumulation of cytoplasmic and nuclear poly(A)⁺ RNAs

DNA region	Cytoplasmic rate (c.p.m. per kilobase per min)	Nuclear rate (c.p.m. per kilobase per min)	Fraction transported*
E2	980	800	1.23
L1	69	75	0.92
L2	10	39	0.26
L3	10	32	0.31

Cytoplasmic rate was determined from the data presented in Fig. 3, and the nuclear rate from the data presented in Fig. 4, in each case using the linear portion of the curves.

* Cytoplasmic rate/nuclear rate.

within the *Bal K* fragment if, in fact, a single termination site exists. However, it is clear that transcription termination prevents expression of at least the final 10 kilobases (map units 70–99) of the late transcription unit during early infection. This is in sharp contrast to the situation late in infection when termination occurs near the end of the genome^{10,15}.

Formation of cytoplasmic mRNA

We measured the rate of accumulation of the first three mRNA families which are included in the first half of the major late transcription unit (see Fig. 1). Infected cells maintained in the presence of cycloheximide were labelled continuously with ³H-uridine from 5 h post-infection. Samples were taken after various times of labelling, and cytoplasmic poly(A)⁺ RNA was prepared and hybridized to DNA probes representing the first three late mRNA families and to a probe for early region 2 as a comparison (Fig. 3). RNA specific to each of these late mRNA families was found accumulating in the cytoplasm although more slowly than that from early region 2. The rates of accumulation were determined for each of the regions using the data presented in Fig. 3 normalized to take into account the sizes of the various DNA probes (Table 2). The L1 family accounted for ~80% of the late RNA accumulating in the cytoplasm during early infection and was about 7% of the rate of the early region 2 mRNA. However, in this particular experiment the rate of transcription of the E2 sequences, as measured in a 10-min ³H-uridine labelling test, was 2.8 times that of the L1 sequences. Thus, after correcting the cytoplasmic accumulation rates for this transcription discrepancy, the L1 mRNA accumulation was 20% the rate of the early region 2. However, even with the correction for relative transcription rates, L2 and L3 mRNA production was well below that of early region 2 (~3%).

Processing of the nuclear RNAs

The preponderance of L1 RNA sequences in the cytoplasm during early infection (a result also seen by others using both electron microscopy¹⁶ or pulse-labelling²⁰) despite equimolar transcription of each of the first three families (see Table 1) implies a post-transcriptional regulation event: either a bias in poly(A) site selection favouring the L1 site or a failure to transport polyadenylated L2 and L3 RNAs to the cytoplasm. This question was analysed by comparing the rates of formation of nuclear and cytoplasmic poly(A)-containing RNAs. The experiment shown in Fig. 3 was also the source for nuclear poly(A)⁺ RNA which was hybridized to DNA probes for the L1, L2 and L3 regions and to a probe for early region 2 (Fig. 4). Clearly, as indicated by the equivalent slopes of the two curves, the early region 2 nuclear poly(A)⁺ RNA was fully converted into cytoplasmic RNA. That is, the rate of accumulation of early region 2 poly(A)-containing nuclear RNA is paralleled closely

in time by an equal rate of accumulation of the sequences in the cytoplasm. An inspection of the accumulation curves of nuclear and cytoplasmic poly(A)-containing RNAs specific to regions L1, L2 and L3 suggested a nearly total conservation of the L1

Fig. 5 Nuclear and cytoplasmic RNAs from early infection detected with L1- and L2-specific probes. Nuclear and cytoplasmic RNA was prepared from cells at 5 h post-infection which had been maintained in cycloheximide (25 µg ml⁻¹). Poly(A)⁺ nuclear and cytoplasmic RNAs and the poly(A)⁻ nuclear RNA were denatured by heating to 65 °C for 5 min in 50% formamide, 1.1 M formaldehyde and 1× RB (20 mM MOPS pH 7.0, 5 mM Na acetate, 1 mM EDTA). After addition of bromophenol blue and glycerol, the samples were loaded on to a 1.5% agarose gel containing 1× RB and 1.1 M formaldehyde. Electrophoresis was at 50 V for about 10 h. The gel was soaked in 20× SSC for 60 min and then blotted to a nitrocellulose sheet (Schleicher & Schuell BA85) according to the method of Southern^{37,38}. The RNAs were detected by hybridization with ³²P *Hind*III IDNA (L1) or *Hind*III D DNA (L2). Plasmid DNAs were labelled by nick-translation to a specific activity of 0.5–1.0 × 10⁸ c.p.m. per µg essentially by the procedure of Rigby *et al.*³⁹. The nitrocellulose sheets were prehybridized overnight in 0.75 M NaCl, 50 mM TESS pH 7.0, 50 mM EDTA, 50% formamide, 5× Denhardt's solution⁴⁰ and 100 µg ml⁻¹ denatured salmon sperm DNA at 45 °C. Hybridization was carried out in the same conditions for 15–20 h but with 1× Denhardt's solution, 100 µg ml⁻¹ salmon sperm DNA and ~1–5 × 10⁶ c.p.m. ml⁻¹ ³²P DNA. After hybridization, the filters were washed successively with hybridization buffer at 45 °C and a final wash with 50% formamide, 10 mM Tris pH 7.4 and 10 mM EDTA at 45 °C for 30 min. The sheets were exposed to preflashed Cronex X-ray film with an intensifying screen for 20–60 h at –70 °C. kb, Kilobases.

Fig. 6 Comparison of L1-specific RNA species produced early and late in infection. *a*, Poly(A)⁺ cytoplasmic RNA was prepared from cells at 5 h post-infection (in the presence of cycloheximide) (E) and 15 h post-infection in the absence of drug (L). The samples were denatured, fractionated in a 1.2% agarose-formaldehyde gel, blotted to nitrocellulose and hybridized with ³²P-labelled *Hind*III I DNA (L1-specific) as described in Fig. 5 legend. *b*, Cells at 5 h post-infection (in the presence of cycloheximide) were labelled with ³H-uridine (200 μ Ci ml⁻¹) for 45 min; cells at 15 h post-infection were labelled with ³²P for 60 min. Poly(A)⁺ cytoplasmic RNA was prepared from each, mixed together and fractionated in a 2.2% acrylamide-0.5% agarose gel³². After electrophoresis, the gel was divided into 2-mm slices, RNA was eluted and then hybridized to filters bearing the *Sma* I fragment (map coordinates 36.7–40.5). Upper panel (○), ³²P late mRNA; lower panel (●), ³H early mRNA. kb, Kilobases.

RNA but a less than complete nuclear to cytoplasmic transport of the L2 and L3 species. Once again, the data were used to determine rates of accumulation for comparison (Table 2). Whereas the L1 sequences accumulated in the cytoplasm at a six- to sevenfold higher rate than for the L2 and L3 sequences, the rates of accumulation in the nucleus for the three regions were within a factor of about two. Thus, the higher rate of appearance of L1 mRNA sequences in the cytoplasm is due to two factors: a bias in the selection of the L1 poly(A) site and a failure to transport all polyadenylated L2 and L3 sequences.

Differential splicing of L1 sequences during early and late infection

Nuclear and cytoplasmic RNA was prepared from cells at 5 h post-infection (in the presence of cycloheximide from the time of infection). The nuclear poly(A)⁺ and poly(A)⁻ RNA and cytoplasmic poly(A)⁺ RNA were electrophoresed in an agarose-formaldehyde gel, transferred to nitrocellulose and analysed by hybridization to a ³²P nick-translated DNA probe specific for the L1 region (Fig. 5). For comparison, L2-specific RNA was also hybridized with a ³²P-labelled *Hind* D probe. Both the probes detected nuclear RNA; the poly(A)⁻ RNAs detected with each probe were mostly less than about 500 nucleotides long, and were presumably breakdown products. Discrete poly(A)⁺ nuclear RNAs were detected. In addition, a discrete species of poly(A)⁺ cytoplasmic RNA, 4.0 kilobases long, was detected with the L1 probe and two species of cytoplasmic RNA, 5.8 and 3.3 kilobases, were detected with the L2-specific probe. However, the L2 cytoplasmic RNA was present in very low abundance compared with the L1-specific RNA, in agreement with the data presented in Fig. 3 and Table 2. The cytoplasmic L1-specific poly(A)⁺ RNA also appeared to be more abundant at steady state than the nuclear poly(A)⁺ L1 RNA, whereas the reverse was true for the L2-specific nuclear and cytoplasmic RNAs. This is consistent with the kinetic analysis result that not all the L2 poly(A)-containing nuclear

RNA is transported to the cytoplasm (see Fig. 4, Table 2). Because of the very low abundance of the L2 RNAs we have not characterized them further.

The finding that only one species of RNA seemed to be formed from the L1 region during early infection was of interest because it contrasted with the situation late in infection where multiple RNAs are formed from this region^{11,12,14}. For a direct comparison, poly(A)⁺ mRNA was prepared from late infected cells and from cells at 5 h post-infection in the presence of cycloheximide. These two samples were then fractionated in an agarose-formaldehyde gel, transferred to nitrocellulose and hybridized with ³²P-*Hind*III I DNA (map coordinates 31.5–37.3) (Fig. 6a). Two major species of late RNA (3.8 and 2.3 kilobases) and two minor species (5.6 and 4.3 kilobases) were detected with the L1 probe. It is possible that the larger of the minor species represents leakage of a precursor molecule from the nucleus. Clearly, however, only one species was detected in the RNA prepared from early infected cells. This RNA was again 4.0 kilobases long and thus did not correspond to any of the RNAs from the late preparation although it may represent the 3.8-kilobase late RNA with an additional leader segment derived from map position 22 as reported by Chow *et al.*¹⁶. Regardless of the actual structure of this RNA, it is clear that the 2.3-kilobase species formed at late times of infection is not produced from the same sequences of DNA early in infection.

However, because this experiment examined only the steady-state population of RNA, we could not say whether the difference was due to differential splicing or differential stability. That is, it was possible that the 2.3-kilobase L1 mRNA was actually formed early in infection but was either not transported to the cytoplasm or was rapidly degraded on reaching the cytoplasm. A failure to transport a properly spliced 2.3-kilobase RNA seems not to be the case because we could not detect this species in the nuclear poly(A)⁺ RNA (Fig. 5) whereas late in infection the 2.3-kilobase RNA could be detected in the nucleus (data not shown). The possibility of rapid cytoplasmic turnover of 2.3-kilobase RNA seemed unlikely as the accumulation data of Fig. 3 gave no indication of instability of the total L1

sequences during 100 min of labelling. Rapid turnover of one half of the L1 mRNA (the 2.3-kilobase species) should have been reflected in the cytoplasmic accumulation curve. However, to answer this question directly, RNA was labelled with ^3H -uridine for 40 min at 5 h post-infection. The poly(A)⁺ cytoplasmic RNA was mixed with a sample of ^{32}P late RNA, fractionated in an acrylamide-agarose gel and hybridized with an L1-specific probe (Fig. 6b). Once again, it was clear that both a 3.8- and a 2.3-kilobase species were formed late in infection. The additional higher molecular weight RNA species detected in this gel represent the minor L1 RNA (Fig. 6a) and the largest RNA of the L2 group because the probe used for this hybridization extends to map position 40.5 (see ref. 12). The pulse-labelled RNA from early-infected cells, however, only contained the 4.0-kilobase species, in agreement with the analysis of steady-state RNA. The clear result both from the pulse-labelled sample and from the steady-state preparations is the absence of the 2.3-kilobase L1 RNA during early infection. Therefore, we conclude that the reason for the qualitative change in L1 RNAs during early and late infection is probably a change in processing at the level of RNA splicing.

Discussion

These results allow us to draw several new conclusions concerning adenovirus gene expression and its regulation. First, the late transcription unit is not under negative control during early infection. Although the rate of transcription of the late transcription unit during early infection is much less than that during late infection, it is still equal to the rate of any of the other early transcription units. Termination of transcription, rather than initiation, may be considered to be a controlling factor in the expression of the late transcription unit during the early phase of infection. Before DNA replication the late transcription unit seems to be active but only to produce RNA corresponding to sequences from the L1, L2 and L3 late mRNA families. Termination of transcription prevents the expression of the remainder of the transcription unit; the mechanism for this event early in infection is not clear although it is noteworthy that transcription proceeds from the late promoter approximately as far as the early region 2 transcription unit. It is possible that the opposing transcription of early region 2 prevents further transcription in the rightward direction and results in termination. This block would then be alleviated late in infection after the synthesis of new viral templates and when early region 2 transcription had been shut off^{22,23}. Alternatively, the termination of transcription in the middle of the genome during early infection or the prevention of this termination late in infection (antitermination) could be an event mediated by a specific factor.

Second, processing in the nucleus of the primary transcripts from the late sequences favours the L1 mRNA region. This is in contrast to the situation during late infection, when the L1

sequences are produced in lowest amounts of the five groups of late mRNAs¹⁵. For instance, during early infection the ratio of L1 to L2 sequence selection in the nucleus is 2:1; however, during late infection the ratio is 1:2. Thus, the process which governs the selection of 3' ends seems to vary according to the conditions of the cell. This finding is also significant in relation to the mechanism by which the poly(A) sites are selected. The finding that the selection of a poly(A) site seems to be changeable implies that the specificity does not reside in the DNA sequence, but rather, that a factor, specific for a given poly(A) site, is responsible for the selection. A change in the concentration of the factor, as a function of time of infection, would then result in changes in the frequency of selection of the possible sites.

Are the processes involved in regulating poly(A) site selection of any importance to the eukaryotic cell? Clearly, such an event could only be valuable to those transcriptional units possessing multiple poly(A) sites. It has recently been shown that the transcription unit for the secreted and membrane-bound IgM heavy chains contains two separate poly(A) addition sites^{24,25}. The basis for selection between those two gene products apparently resides at the choice of the 3' end of the mRNA and could be regulated in their expression by either a termination-anti-termination mechanism or by a changing selection of one of the two sites, as discussed above.

Finally, our results concerning the species of L1 RNAs produced early and late in infection demonstrate that processing, apparently at the level of RNA splicing, can be altered to allow different RNAs to be produced from the same DNA sequence. These results thus indicate that the splicing mechanism changes depending on the environment of the cell (in this case early or late in infection) and therefore can participate in the regulation of gene expression. The nature of the change causing differential splicing is unknown, but clearly involves some difference between an early-infected and a late-infected cell. Recently, there has been much interest in the possible role of the small nuclear RNAs in the splicing of cellular hnRNA^{26,27}. The adenovirus VA RNAs have been postulated to perform a role in splicing of the late viral RNAs in a manner analogous to that proposed for the cellular small nuclear RNA²⁸. If this were true, it may be that early in infection the L1 RNAs are processed utilizing the cellular small nuclear RNA rather than VA RNA. Once VA RNA is formed, the pattern then changes to the set of RNAs observed late in infection. Of course, it is equally possible that a viral protein is required for the splicing reaction which produces the late set of L1 mRNAs. Regardless of the exact nature of the mechanism, it seems clear that a system is available to probe such a question.

We thank Dr J. E. Darnell for helpful discussions, Dr R. Roeder for the clone of the *Sma* F fragment and Dr M. Mathews for the clones of the *Hind*III I and D fragments. We also thank Janet Winkler for technical assistance. This work was supported by NIH grant GM 26765-02. J.R.N. is the recipient of NCI Research Career Development Award CA00666-01.

The AM Herculis-type of dwarf novae have emerged as a new class of cataclysmic variables. They are characterized by fairly steady accretion from a late-type primary on to a strongly magnetized white dwarf. The progenitor of this group, AM Herculis, shows strong optical polarization¹ and prominent emission lines in both the optical² and the UV³. It is also a hard X-ray⁴⁻⁶ and an IR source². Two other X-ray sources, 2A0311-227 (ref. 7) and 2A0526-328 (ref. 8), have recently been suggested as members of the AM Her class on the strength of their similar optical spectra. To compare these objects with AM Her and to extend investigations of this new class of dwarf novae the International Ultraviolet Explorer (IUE) satellite was used to obtain their UV spectra and to search for any changes with the binary motion. We show here that the results confirm the identification of 2A0311-227 with the AM Her class, but not 2A0526-328 which seems to exhibit a UV spectrum more consistent with an SS Cygni type object. Changes in the emission lines' intensities of at least a factor of two were observed as a function of the binary phase.

The IUE observatory⁹ has long wavelength (1,900-3,200 Å) and short wavelength (1,100-1,900 Å) cameras and two resolution modes (10 and 0.2 Å). The images obtained in this observation were taken during an 8-h period starting at 20.00 UT on 24 July 1980 and were all at low resolution and with the large aperture (Table 1). At the time of the observations 2A0526-328 was fainter than $B = 14.5$, while 2A0311-227 was at $B \approx 14.2$. The emission lines were well exposed on both sources and the continua satisfactorily so at least in the case of 2A0526-328. There was, however, some contamination of the long wavelength spectrum of 2A0526-328 at $\lambda > 2,900$ Å probably arising from scattered Earth light.

Figure 1a shows one of the two short wavelength spectra of 2A0311-227. This source has a binary period of 81 min and the data in Fig. 1a were integrated over binary phases 0.6 to 0.1 with phase 0.0 corresponding to maximum light¹⁰. The more prominent line features have been identified and are seen sitting on a fairly flat continuum. This spectrum is very similar to that seen³ from AM Her with all of the spectral lines being common. In general, the UV emission is 5-10 times weaker than in AM Her, which could be partially due to different source distances. The second short wavelength spectrum taken about an hour later over binary phases 0.1 to 0.6 shows the emission lines to be about 40% brighter during this half of the binary cycle. There is no evident change in the level of the continuum, but these images are not well-enough exposed to be too positive about this aspect. The overall shape of the continuum is consistent with a Rayleigh-Jeans $F_{\nu} \propto \nu^{-2}$ law similar to that found by Raymond *et al.* from AM Her. The long wavelength images are almost featureless with no evidence for the interstellar feature at 2,200 Å, indicating that the source distance is ≤ 500 pc.

In contrast, the short wavelength spectrum of 2A0526-328 (Fig. 1b) shows a considerably brighter UV continuum although it is fainter than 2A0311-227 in the optical. Although the emission lines are far less prominent most of the lines visible in

2A0311-227 can also be identified in this source. The significant difference is the presence of absorption or P Cygni profiles seen just resolved in the C IV, S IV and N V resonance lines. These have not been observed in AM Her or 2A0311-227, but some evidence for their existence was found in the UV spectrum of another dwarf nova, SS Cygni, while in an active state¹¹. It is not believed, however, that 2A056-328 was in a particularly bright state during these UV observations because the fine error sensor on board IUE, which has a limiting magnitude⁹ of $B \approx 14.5$, did not detect the source. Charles *et al.*⁸ give its brightness as $V = 13.5$ on 26 October 1978, significantly more than during the current observation. If these absorption features are interpreted in terms of a gas outflow from the system, then an average velocity may be measured for such motion from all the observed features assuming that the absorption and emission components are just resolved. This is found to be $2,000 \pm 600$ km s⁻¹. A second short wavelength spectrum taken about an hour later (the binary period is still uncertain, but is probably in the range 4-5 h (ref. 12)) shows the emission features considerably reduced with only C IV still obvious, but the absorption dips remain essentially unchanged.

The UV continuum of 2A0526-328 is well-fitted by a black body with temperature of $(2.25 \pm 0.1) \times 10^4$ K. This value is similar to that seen by Heap *et al.*¹¹ in SS Cygni who deduced a temperature of 3×10^4 K for this source in its quiescent state. It is also very similar to the black-body temperature of 2.4×10^4 K found by Bath *et al.*¹³ in another X-ray cataclysmic variable, EX

Fig. 1 a, The short wavelength UV spectrum of 2A0311-227 taken by IUE on 25 July 1980. The exposure was 40 min and started at 00.42 UT. b, The short wavelength UV spectrum of 2A0526-328 taken by IUE on 24 July 1980. The exposure was 30 min starting at 21.12 UT. R is a reseau or calibration mark and the large feature at 1,216 Å is due to geocoronal H Ly α emission.

Table 1 Observations carried out during the 8-h IUE shift starting at 20.00 UT on 24 July 1980

Source	Start time (UT)	Exposure (min)	Wavelength	Image no.
2A0526-328	21.12	30	Short	39590
	21.46	30	Long	28336
	22.13	30	Short	39591
2A0311-227	23.40	30	Long	28337
	00.42	40	Short	39592
	01.31	50	Long	28338
	02.44	40	Short	39593

Hydrae. Fitting the $F_{\nu}\nu^2$ law to the continuum of 2A0526-328 is totally unacceptable. However, a $F_{\nu}\nu^{0.3}$ energy distribution predicted from optically thick black-body disk models is generally consistent with these UV observations and the available lower limits on the B magnitude ($B \geq 14.5$). This is another significant difference from the AM Her-type sources where the UV and optical emission seems to arise from different components.

Thus, while 2A0311-227 and 2A0526-328 are both cataclysmic variables their UV spectra show several distinct

differences. The source 2A0311-227 has many similarities with AM Her and is probably a member of this class. Its UV continuum is consistent with $F_{\nu}\nu^2$ and as such probably represents the Raleigh-Jeans tail of a black body peaking in very soft X rays ($E \sim 0.1$ keV). This is similar to the conclusion reached by Raymond *et al.*³ and Fabbiano *et al.*¹⁴ for AM Her. Fabbiano *et al.* conclude that in the case of AM Her the strong magnetic field will give rise to an accretion column as the source of the UV/soft X-ray emission. This will almost certainly also be the case with 2A0311-227 for which one can deduce a comparable magnetic field from its strong optical polarization¹⁵. In the case of 2A0526-328, however, the lack of optical polarization (Tapia, personal communication in ref. 8) together with a rather cooler black-body emission suggests the UV emission is instead arising from an accretion disk. The absorption features further indicate that the whole binary system is immersed in a strong wind emanating from the system. These features make it far more similar to other X-ray cataclysmic variables (which also show no polarization⁸) than to AM Her, and as such emphasize the rather unusual nature of AM Her and 2A0311-227.

We thank the SRC for support, the IUE staff for observational assistance and Dr G. Bromage for helpful advice.

Why is the central gas disk of the Galaxy tilted?

Leo Blitz*, James W.-K. Mark*†

Independent analyses of the HI and CO within 2 kpc of the galactic centre have shown that the gas distribution is best described as a disk-like structure with a rotation axis inclined 20–25° to that of the Galaxy^{1–3}. Detailed models of the gas as an expanding circular disk² or a thin elliptical bar³ describe the observations equally well, but they have no dynamical basis. We propose that the bending wave theory of Bertin and Mark⁴ can provide the dynamical explanation for the tilt, and that the predictions of the theory are independent of the kinematic model of the gas distribution. We show here that the predicted relationship between the disk surface density distribution and the height of the bending are satisfied for both the disk-like and bar-like models of the gas.

The original motivation for the theory^{4–7} was to provide an explanation for the warps in the outer parts of spiral galaxies, and it has satisfactorily explained several observations⁸. The model shows that the warp arises as a self-excited bending wave which is driven unstable because of its motion through the slowly rotating halo. Thus, the disk is rather like a 'flag waving in the wind (of the halo)'. The model described here to explain the tilt in the gas disk near the centre of our Galaxy is similar to this. In

this case, the gas disk moves through the more slowly rotating bulge and an analogous instability results in a 'flapping' of the disk. Direct observations of the bulge component of the galactic nucleus using OH masers related to Mira variables⁹, and IR radiation from population II stars¹⁰, indicate the presence of a slowly rotating spheroidal distribution of stars with a large scale height, comparable to that seen in other galaxies. Liszt and Burton model their CO and HI observations of the central regions of the Galaxy by a massive disk or bar ($> 10^9 M_{\odot}$) with a gaussian scale height of 100 pc and typical rotational velocities of 200–300 km s⁻¹. Thus, the conditions of a thin, rapidly rotating disk embedded within a larger, spheroidal mass distribution treated by the theory are applicable within the central 2 kpc of the Galaxy.

The bending wave theory⁵ predicts a scaling law

$$r^{1/2}\Sigma h \sim \text{constant} \quad (1)$$

where $\Sigma(r)$ and $h(r)$ are the surface mass density and height of bending (or tilt) as a function of radial distance. This scaling law arises because the bending wave propagates with nearly constant rate of outflow of wave energy through circles of radius r ,

$$2\pi r e c_g \sim \text{constant} \quad (2)$$

Equation (1) follows if we note that the wave energy density $\epsilon \propto \Sigma h^2$ and the group velocity $c_g \propto \Sigma$ (for detailed derivation see ref. 5). Although interactions with the bulge slowly amplify this rate of outflow, the amount of amplification per cycle of wave propagation is small and it is the short cycle time which determines the wave growth within the age of the Galaxy.

To examine the constancy of the product $\Sigma r^{1/2}h$, we rely on the detailed models of the nuclear disk for the geometric and kinematic properties of the disk. Burton and Liszt assume a constant surface density in their models and although there is excellent morphological agreement between the predicted and observed moment maps, the agreement between the contour gradients of their model and the observations is not particularly good. We assume that the observed contour gradients provide

Fig. 1 Plot of HI antenna temperature (a quantity proportional to gas density) as a function of the quantity $(r^{1/2}h)^{-1}$ for the circular model (●) and bar-like model (○) described in the text. The dashed lines are least squares fits to the data.

information on the actual run of density of the disk. The observed antenna temperature (T_A) along the line $b = -l \tan 22^\circ$ should provide a good indication of the run of surface density because: (1) This locus of points is the axis of kinematic symmetry (corresponding very nearly to the projected major axis of the circular disk model) and observations along it provide the greatest contrast between the gas in the nuclear disk and the Galaxy at large. (2) The gas is surely optically thin and thus the antenna temperature of the gas should be directly proportional to the volume density. (3) The Burton and Liszt models show good agreement with the observations on the assumption of a disk of constant thickness. If this assumption is approximately correct, the observed HI antenna temperature should give the run of surface density.

To determine the surface density, we used the improved HI observations³ along the line $b = -l \tan 22^\circ$. This line intersects the midplane of the disk-like and bar-like models along a unique locus of points, and we determined the apparent LSR velocity along the locus for both models at 0.5° intervals. From the moment map of the HI observations, we found the HI antenna temperature on both sides of $b = 0$ and averaged the results. Because the data are satisfactorily modelled by a planar distribution with a constant inclination angle the product $\Sigma r^{1/2}h \propto T_A r^{3/2}$ for both the disk-like and bar-like models.

In Fig. 1 we plot T_A as a function of $(r^{1/2}h)^{-1}$ for both models. The points do not differ markedly from a straight line in either case, as expected from the theory. The dashed lines are the least squares fit to the data for each model. The data plotted in Fig. 1 include the HI emission for $l \geq 2^\circ$. Observable CO emission extends to nearly $l = 2^\circ$, and at lower longitudes the H_2 mass is likely to dominate the surface density of the nuclear disk. It is not possible to determine the H_2 mass from CO observations in the nuclear disk with any confidence, and we have therefore excluded the region of $l < 2^\circ$ from our analysis.

It seems reasonable to interpret Fig. 1 as implying that the run of density in the nuclear disk agrees with the predictions of the bending wave theory independently of the kinematics of the model used to describe the data. The largest uncertainty probably comes from the assumption of a constant thickness of the gas layer. The disk-like model could have an increasing scale height due to decreased self-gravity of the disk whereas the bar-like model may have the opposite tendency if it is really a triaxial ellipsoid rather than a thin disk. These possibilities can be tested only with better observations and more refined model making. Nevertheless, for the models we consider, which satisfactorily describe the present observations, the bending-wave theory provides a plausible dynamical basis for the tilt of the nuclear disk.

Radio acoustic measurement of fog-capping thermal inversions

G. Bonino*†, P. P. Lombardini†, A. Longhetto*‡
& P. Trivero*†

The radio acoustic sounding system (RASS) is a remote technique for measuring temperature profiles in the lower troposphere^{1,2}. In essence, it consists of a powerful acoustic source beaming a short burst of sinusoidal waves towards the zenith. The speed of this pulse in its upwards path is proportional at every height to the square root of the local temperature. This speed is continuously measured from the ground by means of a Doppler radar. The radar echo is due to the change in refractive index of air compressed by the acoustic wave. The faint echo is enhanced by choosing an acoustic wave in Bragg resonance with the radio wave. The record of the measured sound speed displayed as a function of delay from the start of the acoustic beam leads to the acquisition of the temperature vertical profile. We now describe the use of such a system at metre-wavelengths in the study of fog-capping thermal inversions at a site in the Po Valley.

Some of our measurements with such a system have been published elsewhere^{3,4}. Comparison with other tropospheric soundings shows that RASS can give temperature profiles between 170 and 1,000 m with an accuracy of $\sim 0.2^\circ\text{C}$ (independent of height) and with a vertical resolution ~ 20 –30 m. The system has the advantages expected of remote sensing devices—short time resolution, rapid measurement and small cost of operation. We have made a particular study of fog-capping temperature inversions because of their importance in determining the fate of airborne pollutants discharged in the thermal plumes from tall industrial chimney stacks.

Since the Summer of 1979, our system has operated on the premises of the thermo-electric power plant of Turbigo. During September 1979, the fourth field experiment on atmospheric

Fig. 1 Comparison of thermal profiles, 13 September 1979, 13 h 30 min: —, RASS; +, radiosonde on disposable balloon (Joint Research Centre); *, measurements at 2 and 145 m height along a smokestack of the power plant.

remote sensing, was carried out by 14 European teams under the auspices of the CEC (Commission of the European Communities) Environmental Research Program, in Turbigo⁵, using radiothermosondes, towed by disposable balloons, tethered balloons, model aircraft, to measure vertical air temperature profiles more or less simultaneously.

The thermal profiles obtained were compared with RASS soundings⁴ as shown in Fig. 1, which includes a temperature profile obtained by the radiothermosonde. Figure 1 shows that RASS data compare favourably with other readings; any local disagreement in the plots is within 0.5 °C, and may be justified by differences in the footprint of the sounding, a few kilometres, and/or the time of measurement. Approximately 100 soundings were compared during the CEC campaign. Limitations associated with this technique are essentially due to strong horizontal winds and large convective vertical motions^{1,6}. Wind shears associated with strong wind distort the acoustic burst which limit the applications of this technique worsens the coherent matching between radio and acoustic waves and causes a lowering of the sounding range. This is not a major drawback in that such conditions ensure a very effective stirring of air and the temperature profile is close to the 'adiabatic lapse rate', which corresponds to a uniform vertical temperature decrease of 0.01 °C m⁻¹.

The temperature error Δt (°C), arising from the effect of the vertical component w (m s⁻¹) of the wind on the RASS measurements, is given by $\Delta t = -1.7 w$. Although this error could cause trouble when evaluating air thermal structure associated with diurnal convective unstable layers, it can be eliminated by using an acoustic radar technique to measure the wind vertical component of velocity independently^{7,8}, or it can be reduced by averaging temperature measurements over suitable periods of time.

In the fog conditions, discussed here, however, these limitations are negligible.

The Turbigo site is located in the centre of the Po Valley, and is characterized by prevailing low wind speed regimes. A non-

uniform thermal structure of the planetary boundary layer (PBL) frequently associated with this meteorological situation, may lead, for example, to nocturnal stable inversion layers, subsidence inversions and fog layers due to water vapour condensation processes. For these cases no prognostic model exists⁹. Consequently, more reliable data from PBL observation are needed, for which knowledge of the vertical thermal profile is important.

One of the most difficult structures of the PBL to measure is the radiative fog layer capped by an elevated thermal inversion of unknown depth and intensity.

We need to know: (1) the thickness of fog layer; (2) the intensity of radiative thermal inversion at the top of fog; (3) the atmospheric stability parameter above the fog-capping inversion, at height 500–1,000 m. SODAR may reveal the first data. The second or third data have to be assessed with disposable radiosondes. However, economy and air traffic regulations impose severe limitations on the latter method.

The present experiment refers to synoptic weather conditions marked by fog in the Po Valley in connection with a high levelled pressure over the Mediterranean area, between 8 and 14 February 1980. On the last day the high pressure promontory weakened, and fog disappeared. Figure 2 and Table 1 show the RASS soundings, balloon soundings from Linate airport and temperature readings along a Turbigo smokestack. The available data from the Linate radiosoundings are only 1–2 between 0 and 1,000 m because these measurements are used for meteorological forecasts and for information regarding air traffic.

Figure 2 shows that: RASS soundings describe the internal thermal structure of PBL up to a high of ~1 km; RASS thermal profile is continuous both in time and in height; vertical resolution and temperature accuracy are satisfactory.

The difference between the thermal profiles on 8 February as deduced by the available Linate radiosonde data and by RASS soundings is interesting. This radiosonde profile would have brought the observer to assume a fairly stable atmosphere above

Fig. 2 Atmospheric temperature vertical profile: —, RASS measurements; O, Linate airport sounding data referred to n th sounding in Table 1; *, measurements at 2 and 145 m height along a smokestack of the power plant; ---, interpolation line connecting experimental points.

Table 1 Atmospheric profiles measured with RASS

RASS profile	Date (February 1980)	Time (p.m.)	Weather conditions	Visibility at Linate airport at 3.00 p.m.	R_H (%)
1	8	4.30	Foggy	400 m	98.7
2	9	4.20	Foggy	600 m	86.8
3	12	12.00	Foggy	1,000 m	97.8
4	13	12.00	Foggy	800 m	98.8
5	14	12.00	Not foggy	4,500 m	78.5

The Linate sounding is always made at 1.00 p.m.

the fog layer, from 300 to 1,000 m. RASS soundings show however, that the stability was not uniformly distributed: a very strong stability between 300 and 400 m being surmounted by a near neutral stratification.

Clearly, such a different representation of the vertical structure of air stability above the fog layer strongly influences pollution forecasts. The radiosonde profiles would have predicted that smoke released by large hot emissions from an elevated point source could be diluted in the higher regions of the PBL. The RASS profile, however, could predict trapping in the capped inversions and hence the danger of a high pollution level.

This example stresses the importance to environmental management of having a reliable vertical thermal profile in real time. RASS has qualities which could fulfil this role.

Low frequency 0.045-Hz swell from the Southern Ocean

F. A. Shillington

Department of Oceanography, University of Cape Town, Rondebosch 7700, South Africa

Unusual, low-frequency, one-dimensional energy spectra of surface gravity waves from measurements with a buoy in deep water (167 m) near Cape Town, South Africa, are discussed here. Classical treatment of the time series of spectra showed that the wave source was 2,800 nautical miles distant and probably in the Southern Ocean. Examination of South African Weather Bureau surface pressure analyses of the South Atlantic depict an intense, slow moving cyclone, with geostrophic wind velocities >50 knots at the same time and place as the origin of the waves. The wave spectra are highly unusual in that they reveal quasi-regular swell at very low frequencies with spectral energy densities an order of magnitude larger than those normally present at these frequencies. The wave event and its associated meteorological conditions are also discussed.

Surface gravity waves have been measured on a regular basis from positions near Cape Town, South Africa, for several years¹⁻³. These sites are open to waves from the South Atlantic and Southern Ocean. Because long fetches are possible to the south and west of South Africa, it is accepted that the peak

Fig. 1 Energy-frequency-time diagram with days marked at 12 h GMT and wave energy contours in dB above $1 \text{ m}^2 \text{ s}$.

frequency of the wave spectra is often low (between 0.06 and 0.10 Hz). However, it is rare to measure significant wave energy in frequency bands with the central frequency lower than 0.05 Hz (period 20 s). This is the third such occurrence (see refs 1, 2) in ~8 yr of measurements. The signature of the event in the energy-frequency-time space and the local height of these low frequency waves rules out the explanation that the storm has originated in the Northern Hemisphere as do the Saint Helena rollers described by Cartwright *et al.*⁴.

The wave recordings were made with a Datawell waverider buoy every 6 h for 20-min intervals. Two buoys are maintained: one in a depth of 167 m of water and the other in 20 m of water. The contours of energy in frequency-time space were similar for both buoys. Only the measurements from the deep buoy are presented, as these are free from bottom effects. Spectral values were computed by standard FFT techniques from 17-min long time series sampled every 0.5 s. The estimates have 20 d.f. with 80% confidence levels of 0.62 and 1.42 times the estimates. Frequency resolution is 0.0098 Hz. The spectra have been plotted to give an energy-frequency-time plot (see Fig. 1), with contours of wave energy density at logarithmic intervals.

Assuming that the storm-wave generation area is small compared with its distance from the recorder, classic treatment of the spectra shows that there will be a linear increase of swell frequency with time. If t_0 is the time of origin of such swell, the distance, D , of the generating area can be determined by extrapolating the slope ($\Delta f / \Delta t$) of the 'ridge' in Fig. 1 back to the zero frequency axis and noting that the group velocity of waves

Fig. 2 The South African Weather Bureau synoptic surface pressure analysis for 12 h GMT 29 July 1980. Contours are at 4-mbar intervals and the probable fetch for the waves is hatched. The map projection is polar stereographic.

of frequency f is

$$Cg = \frac{g}{4\pi f}$$

so that

$$D = g / \left(4\pi \cdot \frac{\Delta f}{\Delta t} \right).$$

Using this technique, we find that the wave source origin was at 00 h GMT, 29 July 1980, 2,800 nautical miles from the recorder (Cape Town). The lowest frequency identifiable as a definite peak is at 0.045 Hz; these waves travel at 800 nautical miles per day and reached the wave recorder at 12 h GMT on 1 August 1980. Slower moving 0.06 Hz waves arrived one day later at 12 h GMT.

The normal source area of wave events directed towards Cape Town is the South Atlantic. Examination of the South African Weather Bureau synoptic forecast weather surface pressure charts revealed an intense depression centred at 55°S, 35°W at 00 h GMT, 29 July 1980 (see Fig. 2). The central pressure of this cyclone deepened from 964 to 956 mbar in the 24 h from 12 h 28 July to 12 h 29 July. A further deepening of the low to 948 mbar occurred on 30 July. The storm track followed a course to the south-east with the centre being at 68°S on 1 August 1980 (see Fig. 3). At this time, winds within 1,000 miles of Cape Town were from the south-east and unfavourable for the generation of long period waves. Geostrophic wind-speeds higher than 50 knots are evident on the chart (Fig. 2).

What windspeed is required to generate waves with a peak frequency of 0.045 Hz? The present method follows Pierson and Moskowitz⁶ who showed that for a fully developed sea, the peak frequency (f_m) and windspeed are (U) related by

$$f_m = 1.37 U^{-1} \quad (U \text{ measured at 10 m height, in } m s^{-1}, f_m \text{ in Hz}).$$

For $f_m = 0.045$ Hz, $U = 30.4 m s^{-1}$ that is, a 60-knot wind is required to generate a fully developed spectrum with a peak frequency of 0.045 Hz.

As a fully developed spectrum was not measured, the present calculation is based on the work of Hasselmann *et al.*⁷ to find the size of fetch that would produce a wave spectrum with a peak at $f_m = 0.045$ Hz. The empirical equation found from the JONSWAP⁷ data relates the dimensionless peak frequency $\tilde{f}$ to the dimensionless fetch $\tilde{x}$ by

$$\tilde{f} = 3.5 \tilde{x}^{-0.33}$$

where

$$\tilde{f} = \frac{f_m U}{g} \quad \text{and} \quad \tilde{x} = \frac{xg}{U^2}$$

For $U = 30 m s^{-1}$, $\tilde{f} = 0.138$ and $\tilde{x} = 1.64 \times 10^4$. The length of the fetch is 1,500 km. These values place the results at the limit of the JONSWAP data set⁷.

Using $\tilde{x}$ above and the work of Mitsuyasu and Rikiishi⁸, the minimum duration required to generate a spectrum with a peak frequency of 0.045 Hz with a fetch of 1,500 km, is 23 h. Again,

Fig. 3 Chart with storm track and storm centre locations together with wave travel time and positions of 0.045 Hz and 0.06 Hz components.

because the work cited⁸ is for small dimensionless fetches, extrapolation to larger fetches might be dangerous.

If these large orders of magnitude for the windspeed, fetch and duration are required to generate the observed wave conditions ($U = 30 \text{ m s}^{-1}$, fetch = 1,500 km, duration = 23 h), then even if it was not unusual to find deep, low pressure cyclones in this part of the Southern Ocean⁹, it would be exceptionally rare to get a fetch of the order of 1,000 km with sustained 60-knot winds for a period of a day, generating waves in one particular direction. Careful examination of one year's wave spectra recorded at South Uist in the Outer Hebrides¹⁰ at latitude 57°N, longitude 8°W, shows that the spectral energies reported here were a factor of two greater at 0.045 Hz than any of those at South Uist. The dangers of extrapolating measurements^{7,8} beyond their respective domains are accepted, but with the limited data available, it seemed to be the only logical approach.

I thank the Council for Scientific and Industrial Research's National Research Institute for Oceanology, Stellenbosch and the Fisheries Development Corporation for maintenance of equipment and availability of the deep sea data. The work was funded in part by the South African Committee for Oceanographic Research.

Changes of ^2H and ^{18}O enrichment of meteoric water and Pleistocene glaciation

Russell S. Harmon

Henry P. Schwarcz

Department of Geology, McMaster University, Hamilton, Ontario, Canada L8S 4M1

Recent theoretical modelling¹ has suggested that the well documented δD – $\delta^{18}\text{O}$ relationship for modern meteoric waters may have changed during the Pleistocene glacial periods in response to increased ocean surface air humidity. Here we present isotopic data on fluid inclusions and host speleothems which support this hypothesis. Depositional temperatures can be determined for speleothems formed in equilibrium conditions from the temperature dependence of the calcite–water ^{18}O fractionation by isotopic analysis of both entrapped fluid inclusions and host calcite. Palaeotemperatures for five areas of east-central North America and Bermuda, calculated assuming the present δD – $\delta^{18}\text{O}$ meteoric water relationship for fluid inclusion waters, are observed to be too low during late Pleistocene glacial periods, in some instances falling below 0 °C. By contrast, interglacial palaeotemperatures are largely equivalent to those in the areas at present. As speleothem deposition cannot occur at subzero temperatures, a possible solution to this dilemma is a shift in the intercept of the meteoric water relationship.

The stable isotopic composition of most coastal and continental meteoric waters not subjected to extensive evaporation form a linear array (Fig. 1a) best described by the relationship:

$$\delta\text{D} = X\delta^{18}\text{O} + d_0 \quad (1)$$

where $X = 8.0$ and d_0 , the so-called deuterium deficiency, is +10‰ (refs 2, 3). This correlated behaviour of D and ^{18}O variations in the hydrosphere results from both equilibrium and kinetic effects which occur during the processes of evaporation and condensation in the atmosphere^{1–4}. Liquid–vapour fractionations are such that vapour evaporated from the ocean is proportionally depleted in D and ^{18}O . Water subsequently condensed in the atmosphere will be enriched in both heavy isotopes to an extent determined by the isotopic composition of the vapour source and the temperature at the time of condensation. Thus, precipitation from an air mass moving away from its tropical oceanic source towards higher latitudes will become progressively depleted in D and ^{18}O , producing a pronounced and characteristic geographic distribution in the isotopic composition of continental precipitation (Fig. 1b). This natural evaporation–condensation cycle can be modelled in terms of a Rayleigh distillation process, the slope of the δD – $\delta^{18}\text{O}$ relationship in equation (1) being characteristic of liquid–vapour equilibrium^{1–3} and the intercept d_0 , indicative of the extent to which kinetic processes have affected the system.

At present this general, worldwide δD – $\delta^{18}\text{O}$ relationship is determined by the isotopic composition of the ocean, the ultimate source of all continental precipitation, as well as the prevailing climatic conditions in which evaporation and condensation occur. During the last glacial maximum at 18,000 yr BP the ocean was enriched in ^{18}O by ~1.1–1.4‰ (ref. 5); the corresponding shift in δD is undetermined at present, but was presumably close to +10‰. If prevailing climate conditions change so as to amplify or diminish kinetic fractionation during evaporation or condensation, d_0 will be altered. The data we present here suggest that this may have been the case during the Pleistocene ice ages.

Oxygen isotope variations in calcite speleothems can yield a relative record of past climatic fluctuations if deposition occurred in conditions of isotopic equilibrium with their parent seepage waters^{6–8}. Moreover, if the ^{18}O content of the parent seepage can be estimated from analysis of fluid inclusion trapped within a speleothem at the time of deposition⁹, then the temperature of deposition can be calculated from the temperature dependence of the calcite–water ^{18}O fractionation as given by O'Neil *et al.*^{10,11}:

$$10^3 \ln \alpha_{c-w} = 2.78 \times 10^6 T^{-2} + 2.89 \quad (2)$$

where $\alpha_{c-w} = (\delta^{18}\text{O}_{\text{calcite}} + 1,000) / (\delta^{18}\text{O}_{\text{water}} + 1,000)$. Inasmuch as the temperature deep within a cave is related to the long-term, average temperature on the surface above the cave, such isotopic palaeotemperatures should reflect surface temperature variations throughout the period over which the speleothem was deposited.

Direct analysis of the ^{18}O composition of fluid inclusion waters has not yet been satisfactorily demonstrated, the two major problems being the possibility of continued isotopic exchange between the host calcite and water subsequent to entrapment and that of exchange induced during crushing and extraction for analysis. It has previously been shown, however, that the D and ^{18}O contents of modern cave seepage in temperate areas of North America and western Europe are equivalent to the surface precipitation from which the ground-water seepage was derived^{9,12,13} (Fig. 1a). It should therefore be possible using equation (1) to estimate the $^{18}\text{O}/^{16}\text{O}$ ratio of speleothem fluid inclusion waters from an analysis of the D/H ratio. Table 1 shows the observed agreement both between the $^{18}\text{O}/^{16}\text{O}$ ratios calculated for fluid inclusion waters from modern

$\delta^{18}\text{O}_c$ is measured speleothem calcite $^{18}\text{O}/^{16}\text{O}$ ratio.

$\delta^{18}\text{O}_n$ is calculated fluid inclusion $^{18}\text{O}/^{16}\text{O}$ ratio from equation (1).

$\delta^{18}\text{O}_w$ is measured water $^{18}\text{O}/^{16}\text{O}$ ratio.

δD_n is measured fluid inclusion D/H ratio.

Isotopic temperature is temperature calculated from equation (2).

Number of samples analysed are given in parenthesis.

* Data from ref. 28.

stalagmites and that measured for cave seepage waters and also between calculated isotopic temperatures for these speleothem-fluid inclusion pairs and measured cave temperatures. In both cases the differences are just slightly larger than the limits of the analytical uncertainty. Using the procedures described in ref. 14, D/H ratio measurements for speleothem fluid inclusions

have a precision of about $\pm 3\%$, whereas speleothem calcite $^{18}\text{O}/^{16}\text{O}$ ratio determinations have a precision of $\pm 0.1\%$. This translates to an overall uncertainty of about ± 2 to 3°C in estimated palaeotemperatures, given the inherent small-scale inhomogeneities in the volume of speleothem material used for an individual analysis. This uncertainty, though substantial, is

Fig. 1 a, Relationships between D/H and $^{18}\text{O}/^{16}\text{O}$ variations in various modern meteoric waters^{2,3}. Specific fields shown are those for modern Antarctic precipitation^{20,21}, post-glacial and glacial age ice from Byrd Station, Antarctica¹⁹, modern seepage waters in caves of east-central North America^{9,12,15} modern and palaeo groundwaters in North Africa²²⁻²⁴ and modern seawater^{25,26}. Modern meteoric waters are best described by the relationship $\delta\text{D} = 8\delta^{18}\text{O} + 10$ whereas that for glacial-age meteoric waters appears to be $\delta\text{D} = 8\delta^{18}\text{O}$. b, Map of North America showing approximate δD contours for meteoric surface waters (after Taylor)²⁷. Also shown by the North American sample localities discussed in the text.

Age is interpolated age estimated from $^{230}\text{Th}/^{234}\text{U}$ dates on two or more horizons within the speleothem, assuming constant linear growth rate. $\delta^{18}\text{O}_c$ is measured oxygen isotopic composition of calcite. δD_w is measured hydrogen isotopic composition of fluid inclusion water. $\delta^{18}\text{O}_w^*$ is calculated oxygen isotope ratio of inclusion water assuming $\delta\text{D}_w = 8\delta^{18}\text{O}_w + 10$. $\delta^{18}\text{O}_w^{**}$ is calculated oxygen isotope ratio of inclusion water assuming $\delta\text{D} = 8\delta^{18}\text{O}_w$. T^* is isotopic temperature calculated from $\delta^{18}\text{O}_c$ and $\delta^{18}\text{O}_w^*$ using equation (2). T^{**} is isotopic temperature calculated from $\delta^{18}\text{O}_c$ and $\delta^{18}\text{O}_w^{**}$ using equation (2).

† For Bermuda we have assumed that for modern and interglacial precipitation: $\delta\text{D} = 6\delta^{18}\text{O} + 4.2$ while for transitional and glacial times: $\delta\text{D} = 6\delta^{18}\text{O}$ (see refs 9, 13).

‡ A climatic classification of the samples was constructed from a correlation of their ages with the foraminiferal isotopic record of deep-sea core V23-238⁵ for which a time scale has been established from the position of the ~730,000 yr BP. Brunhes–Matuyama magnetic reversal and the assumption of a constant sedimentation rate throughout the core. $\delta^{18}\text{O}$ values of foraminifera ($\delta^{18}\text{O}_f$) increase with increasing ice volume because of the increase in $\delta^{18}\text{O}$ of the ocean and lower oceanic temperatures during glacial periods. Thus speleothems deposited at times when $\delta^{18}\text{O}_f > -1.25\text{‰}$ are called glacial (g); when $\delta^{18}\text{O}_f < -1.70\text{‰}$ we have interglacial (i) conditions; between these limits we refer to the climate as intermediate (t).

smaller than the 4–14 °C temperature difference postulated from climate reconstruction for east-central North America during the 18,000 yr BP Wisconsinan glacial maximum¹⁵. This technique should, therefore, be applicable to ancient speleothems where it would have the potential to provide a proxy record of late Pleistocene terrestrial climate change which is otherwise difficult to obtain.

Isotopic data for 11 late Pleistocene speleothems deposited in equilibrium conditions within caves in east-central North America and Bermuda are given in Table 2. Ages for individual calcite–fluid inclusion pairs were interpolated from growth

curves established by $^{230}\text{Th}/^{234}\text{U}$ dating of multiple horizons within the speleothem¹⁶.

We have previously shown that fluid inclusions from five of these speleothems became depleted in deuterium as climate shifted from interglacial to glacial conditions¹⁵; the average shift in δD in north-central North America was about -12‰. Palaeotemperatures calculated using equation (1) for these five samples and six additional ones are presented in Table 2. While most palaeotemperatures range between modern values at a site and 0 °C, in some instances they fall below 0 °C (for example, Iowa) and in others are clearly too low considering the

geographic location of the cave sites (for example, Texas and Bermuda).

Groundwater recharge and calcite precipitation cannot occur when cave temperature is below freezing. Groundwater recharge is possible in certain permafrost conditions where the annual average surface temperature is below 0 °C, such as in the high Arctic at present¹⁷, and cave temperatures may be maintained above freezing in an area where the average surface temperature is subzero¹⁸. These situations, however, represent arctic and alpine anomalies unrelated to the temperate lowland and marine karst areas, under discussion here. Therefore, we consider the very presence of a speleothem deposit as evidence that the cave temperature was above the freezing point during the time of its deposition.

A possible resolution of this dilemma is that equation (1) changed during Pleistocene glacial periods. The general δD - $\delta^{18}O$ meteoric water relationship is geographically somewhat variable at present³. For example, precipitation in Japan and the Mediterranean is displaced to lower $\delta^{18}O$ values by ~1.5% relative to other meteoric waters with an equivalent δD value, while for most oceanic islands the relationship is $\delta D = 4.2\delta^{18}O + 0.1$. More significantly, temporal variation in the δD - $\delta^{18}O$ relationship was noted by Epstein *et al.*¹⁹ in their study of the ice core from Byrd Station, Antarctica. Here post-glacial precipitation falls on the $\delta D = 8\delta^{18}O + 10$ line as does modern precipitation^{20,21}, whereas glacial-age precipitation is best described by the relationship $D = 7.9\delta^{18}O$ (Fig. 1a). Our data are compatible with the idea that Pleistocene meteoric waters elsewhere also exhibited a relative deuterium deficiency during glacial periods. Thus during glacial periods, $X \approx 8$ and $d_0 \approx 0$ with d_0 approaching its present value of +10 during transitions from glacial to interglacial climate.

Independent evidence for such changes in d_0 is provided by hydrologic studies in North Africa²²⁻²⁴ where low- ^{14}C (Pleistocene-age) groundwaters have been observed with $d_0 = 0$, whereas for modern precipitation $d_0 \approx 10$ (Fig. 1a). It therefore seems that during at least the last glacial period of the Pleistocene $X \leq 8$ and d_0 was significantly less than 10; both variables acquiring the present value (8, 10) shortly after the present interglacial period began some 10,000 yr ago.

We have recalculated temperatures for speleothem samples deposited during glacial and transitional periods assuming the extreme boundary conditions of $X = 8$ and $d_0 = 0$ (Table 2). In so doing, all isotopic temperatures become positive and those for the southerly cave sites become climatologically more reasonable. For example, values of ΔT for the Iowa (-5 to -7 °C), Kentucky (-3 to -8 °C), and Texas (-11 to -16 °C) sites are in close agreement with those derived for the Great Lakes (-7 to -11 °C), Interior Lowlands (~-13 °C), and southwestern v.s. (-11 to -13 °C) regions from the ice-age climate modelling of Gates¹⁵ based on the CLIMAP²⁹ data, and not substantially different from those for the Great Lakes (-6 to -14 °C) and Appalachian Regions (8 °C) estimated by Peterson *et al.*³⁰ from pollen data. Of the six data sets in Table 2, that for Iowa is the most important because the Coldwater Cave stalagmite not only has the highest growth rate and smallest age uncertainties of any of the samples analysed, but also was deposited during the period of the change from the full glacial conditions of the late Wisconsinan to the interglacial conditions of the Holocene. The well-defined trend towards lower isotopic temperatures during the late Wisconsinan glaciation and the virtual coincidence of the speleothem temperature minimum and the glacial maximum at 18,000 yr BP give us confidence in these results. However, the data for the older speleothems must be considered inherently less accurate because of the larger uncertainties in dating. This especially applies to individual samples of 'intermediate-type' whose ages lie near climatic boundaries and thus may be misclassified as to climate type. The situation in Bermuda is different and more complex than in the continental sites and as a result somewhat problematic. Here, modern precipitation lies on a line of lower slope and d_0 value ($\delta D = 6\delta^{18}O + 4.2$, ref. 13). Because d_0 should in theory be zero

or positive depending on whether evaporation occurs totally in equilibrium or kinetic conditions¹, the glacial-age palaeotemperatures calculated for Bermuda in Table 2 are calculated for Bermuda in Table 2 assuming only a -4.2% shift in d_0 , while X is presumed to remain constant. Also, the Bermudian speleothems analysed were all formed at elevations below present sea level in presently flooded caves, so that none record fully interglacial conditions at this site.

The average difference between modern and ancient temperatures (ΔT) is negative and greatest for deposits formed during glacial times (Table 2). The apparently low ΔT values observed for some 'intermediate' samples presumably reflects the fact that we have set $d_0 = 0$ for these samples whereas during these times the true d_0 value was between 0 and +10. Without some estimate of both the $^{18}O/^{16}O$ and D/H ratios of glacial-age waters it is not possible to define the exact δD - $\delta^{18}O$ relationship. However, as long as the relationship remains linear with a slope $d\delta D/d\delta^{18}O = 8$, then small changes in the intercept d_0 will only have a comparatively small effect on the calculated temperature difference, ΔT . Using a global model of oceanic evaporation and precipitation, Merlivat and Jouzel¹ find that d_0 is virtually independent of the temperature at the site of evaporation, but decreases linearly with increasing relative humidity at the source site. A value of $d_0 = 0$ would correspond to a relative humidity of subtropical oceanic air of about 100% compared with a value of 81% at present. Growth of continental ice sheets might also have had an effect on the δD - $\delta^{18}O$ relationship due to the consequent enrichment of both D and ^{18}O in seawater.

It would thus seem important to obtain independent measurements of both $^{18}O/^{16}O$ and D/H ratios in dated Pleistocene palaeowaters, to evaluate the possibility of secular changes in the δD - $\delta^{18}O$ relationship for meteoric waters. Such work is in progress in the McMaster laboratory. Similar detailed studies on other ice cores are also required.

This research was funded by grants from the Climate Dynamics Programme of the NSF (ATM77-20365) and by the National Research Council (Canada). Support from the National Speleological Society and Cave Research Foundation is also acknowledged. We thank L. F. Binney, D. White, M. Boska and J. Borthwick for laboratory assistance, S. Epstein, J. R. O'Neil and J. Gray in whose laboratories some of the D/H ratio measurements were made, and N. J. Shackleton, and T. C. Atkinson for critical comments. Manuscript typed by Mrs E. Yuill and illustrations prepared by J. Bennett.

Two orogenies in the Grenville Belt?

A. J. Baer

Department of Geology, University of Ottawa, Ottawa, Canada K1N 6N5

The age of the Grenvillian event is commonly taken to be ~1,000 Myr, but depending on the isotopic systems used and the rocks examined, dates vary from 1,100 Myr or more¹ to ~700 Myr (ref. 2). K-Ar mineral dates and ⁴⁰Ar/³⁹Ar dates reflect blocking temperatures that correspond to regional cooling. They should, therefore, be younger than the true age of a thermal event that would be more accurately dated by Rb-Sr whole-rock isochrons or by U-Pb dating of zircons. However, because blocking temperature for argon is estimated to be 550–600 °C in hornblende³, hornblende dates should at least correspond to the time at which medium to high-grade metamorphism was last reached in the rock if systems have remained closed ever since. In the Grenville Province, the discrepancy between ~1,100 and ~950 Myr dates recorded by different radiometric clocks has commonly been attributed to a progressive and slow cooling of the region⁴. I suggest here that the presence of at least two distinct thermal events in that time interval is a plausible explanation.

It has been shown both experimentally⁵ and theoretically⁶ that different minerals have different blocking temperatures for Ar and Sr, and this property has been used to unravel the evolution of complex polymetamorphic crystalline terrains⁷. In the western Grenville Province, numerous such cases have been documented of K-Ar mineral ages at ~1,000 Myr BP whereas Rb-Sr whole-rock isochrons ran from 1,400 to 2,350 Myr BP (refs 8, 9). At least two distinct thermal events (Hudsonian and Grenvillian) have been thought to affect the region. There are other cases, however, and more particularly in the central part of the Grenville Province, where 40% of U-Pb dates on zircons and Rb-Sr whole-rock isochrons cluster around 1,050–1,100 Myr whereas 18% coincide with the peak of K-Ar dates at 900–950 Myr. A similar difference of ~150 Myr is also found in some K-Ar determinations of hornblende-biotite pairs from the same area (Table 1). Is this due to slow cooling?

Two peaks of K-Ar dates have been found^{10,11} from the Grenville Province and there are two possible interpretations. At the time, the lack of Rb-Sr whole-rock isochrons and U-Pb zircon dates corresponding to the younger K-Ar peak seemed to favour a slow cooling interpretation. Since then most authors have assumed that isostatic re-equilibration and erosion following orogenic activity could explain a 150 Myr time-lag between Rb-Sr whole-rock dates and K-Ar dates.

The determination of which length of time justifiably represents slow cooling, and which one separates two events is difficult. Blocking temperatures in metamorphic terrain are controlled by uplift of large crustal blocks⁴. In the Grenville, from metamorphic mineral assemblages the total crustal thickness during the Grenvillian event must have reached 60–70 km (ref. 12). By isostatic adjustment this must have caused the formation of an elevated belt as high as the Tibetan Plateau. Speed of erosion of this belt would control its rate of cooling. Calculations of recent cooling rates in the Alps give values varying from 50 °C Myr⁻¹, 29–26 Myr ago to 6 °C Myr⁻¹ for the past 14 Myr (ref. 13). Estimates based on rates of erosion and on an assumed geothermal gradient of 40 °C km⁻¹ yield values of 32–16 °C Myr⁻¹ at present¹⁴. Because cooling curves seem to be strongly exponential over a few tens of million years these values are certainly minimum figures. In the Grenville Province, dating of hornblende and biotite pairs by the ³⁹Ar/⁴⁰Ar technique indicates ~30–50 Myr between blocking temperatures of the two minerals^{3,15,16}, corresponding therefore to a cooling rate of

6–10 °C Myr⁻¹, in reasonable agreement with alpine estimates, if somewhat on the low side. If blocking temperature for argon in hornblende is of the order of 550–600 °C, the cooling of medium- to high-grade metamorphic rocks to ~300 °C should commonly take 50 Myr. However, given the accuracy of most available K-Ar dates, this time gap is too small to be statistically significant. Specific cases have been reported, however, where discrepancy between various dates cannot be explained by differences in cooling rates. For instance, in Lac Croche area Rb-Sr whole-rock isochrons show the peak of regional metamorphism and deformation to date from ~1,100 Myr ago (1,100 ± 27; 1,070 ± 43) whereas formation of a younger (metasomatic?) granite was dated from 940 ± 20 Myr by the same method¹. K-Ar dates on micas in gneisses give 955 Myr. In three other areas, hundreds of kilometres apart, in Cardiff and Mont Laurier in the Central Gneiss Belt and in Johan Baetz area in the eastern Grenville Province, uranium-bearing pegmatites have been dated from ~950 Myr ago (Rb-Sr whole-rock isochron method) whereas the peak of metamorphism dates from 1,100 to 1,050 Myr ago (same dating method applied to surrounding granites)¹⁷. Fowler and Doig¹⁷ report that uraniferous granites "seem to have crystallized from melts produced after the main pulse of the Grenville orogeny rather than through processes of *in situ* anatexis or metasomatism". In other words, geologically younger granitic rocks are isotopically distinct from and ~150 Myr younger than adjacent rocks. Finally, recent dating of the Marcy anorthosite in the Adirondacks gives 1,190 ± 130 Myr by the Sm-Nd method and 930 ± 40 Myr by the Rb-Sr whole-rock isochron method on the same samples¹⁸.

How general is the distribution of these two temporally distinct events? K-Ar dates in the 900–950 Myr range are distributed throughout the Province, but 1,050–1,100 Myr Rb-Sr whole-rock isochrons and U-Pb zircon dates are concentrated in a northeasterly trending swath in the central part of the Province only (Fig. 2). West of a line running from Bancroft to Chibougamau, Rb-Sr whole-rock isochrons reflect still older thermal events extending back in time to the Archean^{8,9,19–22}. Thus, in the western Grenville Province the absence of a 1,100 Myr set of dates apparently means that the 950 Myr dates stand on their own, and do not represent the end of a long cooling phase. Previous thermal events of high intensity last affected the area around 1,300 Myr or earlier⁹.

Outside Canada, two distinct radiometric events have been reported from the Adirondacks (1,100 and 850–900 Myr)^{23,24}, from east Greenland (1,150 and 950 Myr)^{25,26}, from southern Norway (1,100 and 900–100 Myr)^{27,28} and from the basement of the Appalachians (1,150 and 835 Myr)^{11,29}. Dates from Skåne in

Fig. 1 Histogram of isotopic ages in the Grenville Province.

Table 1 Comparison of isotopic ages from some areas inside and outside the Grenville Province

Outside the Grenville Belt					
	U-Pb (Myr)	Rb-Sr whole-rock isochron (Myr)	K-Ar mica (Myr)	K-Ar amphibole (Myr)	Maximum difference (Myr)
Basler Lake		2,510 ± 106 ³⁷	2,460, 2,420, 2,390 ³⁷		120
Nueltin Lake		1,775 ± 59 ³⁷	1,800, 1,735 ^{32,38}		25
Mistastin Lake		1,318 ± 15 ³⁹	1,340 ⁴⁰	1,325 ⁴⁰	17
Umiakovik Lake		1,290 ± 30 ⁴¹	1,275 ⁴²		15
Inside the Grenville Belt

Deloro pluton		1,096 ± 46 ³⁷		989 ¹⁰ , 875 ⁴⁰	221
Labrieville		1,165 ± 90 ⁴⁸	875 ⁴²		290
Reading Prong	1,060 ⁴⁹		788 ⁴⁶	873 ⁴⁶	272
New Jersey Highlands	1,170 ¹¹		905 ¹¹		265

All Rb-Sr dates recalculated for $\lambda = 1.42 \times 10^{-11} \text{ yr}^{-1}$.

Sweden suggest similar relationships, but results are somewhat ambiguous³⁰. This remarkable persistence of two peaks of thermal activity throws some doubt on an interpretation involving slow uplift and cooling and it suggests that the possible existence of two thermotectonic events should be carefully evaluated. This would mean that an early Grenvillian event would only have affected some parts of the Grenville Belt, and a later event, of lesser intensity but greater areal extent would be responsible for the later group of dates.

In Scandinavia regional metamorphism and deformation peaked around 1,200 Myr ago, and again around 1,000 Myr ago²⁸. According to Berthelsen (personal communication) early Grenvillian structures (Ostfoldian) trend north, with a westerly vergence, and later structures cut across them. Structural trends are similar in both cases but the younger thrust planes dip west instead of east. In Canada, early Grenvillian Rb-Sr isochron dates fall in a zone of north-northeasterly structures that run obliquely to the Grenville Front (Fig. 2). This penetrative structural grain contrasts with a variety of trends in other parts of the Province and suggests that the earlier event was more homogeneous and more intense than the later one. The latter did not generally open Rb-Sr whole-rock systems, and in places it did not even reset K-Ar mineral dates (1,533 ± 42 Myr on hornblende³¹ and 1,395 Myr on biotite³² for example).

If the distribution of 'Grenvillian' dates corresponds to two events 150 Myr apart, thermochrons⁴ drawn from the distribution of all K-Ar biotite dates are meaningless. In fact, one cannot draw continuous thermochrons for either a 1,100–1,150 Myr group or a 850–1,000 Myr group of K-Ar dates on biotites.

Fig. 2 Distribution of 1,100 ± 50 Myr Rb-Sr whole-rock isochron dates in the Grenville Province. Dots correspond to isochrons giving older dates. Note coincidence of north-northeasterly structural trends with rocks dated at 1,100 ± 50 Myr dates. * R. K. Wanless (personal communication).

The available geochronological data suggest therefore, to a first approximation, that the Grenvillian thermal activity extended from ~1,150 to 850 Myr ago. Considerations of argon retention by various minerals and of the significance of Rb–Sr whole-rock isochron and U–Pb zircon dates suggest either that metamorphism peaked around 1,100 Myr ago and that all younger dates represent a tail-end of this same event, or that two distinct metamorphic events took place, a stronger one around 1,100 Myr ago and a weaker one around 900 Myr ago. If 'slow cooling' is the explanation and is taken to mean a cooling rate of ~300 °C between 1,150 and 950 Myr ago, this is one order of magnitude slower than present cooling rates in the Alps. If cooling is in turn dependent on rates of isostatic uplift and of erosion, slow uplift and slow erosion of a very thick continental crust seem to contradict what we know of crustal isostasy. The other possible explanation is that of two distinct events. This would explain why some Rb–Sr whole-rock isochron dates and U–Pb zircon dates are identical to K–Ar biotite dates whereas others differ by 200 Myr (Table 2). In this interpretation, the younger event would have affected all the belt but may not have been strictly coeval everywhere, because dates reported from the southern Appalachians (700–750 Myr)² are considerably younger than those from the northern Appalachians^{11,29,33}, Canada^{34,35} and Scandinavia (800–900 Myr)^{28,30,36}. The older events would have been of more restricted extent but, at least in the central Grenville Province, deformation was intense enough to give a common structural grain to the region (Fig. 2). Figure 1 summarizes the argument. Rb–Sr whole-rock and U–Pb dates on zircon form two peaks. The older is higher because dates were generally not reset by the second event. K–Ar dates form one peak that coincides with the younger of the previous two. The K–Ar histogram is asymmetric, suggesting the existence of a set of older dates partly reset by the younger event.

I thank K. Bell, G. W. Berger, R. D. Dallmeyer and W. K. Fyson for constructive comments, E. Hearn for drawing the figures, S. Meunier and H. DeGouffe for typing the text.

A Pleistocene lacustrine episode in southeastern Libya

C. Gaven, C. Hillaire-Marcel & N. Petit-Maire

Centre National de la Recherche Scientifique, Laboratoire de Géologie du Quaternaire, Faculté des Sciences de Luminy-Case 907, 13288 Marseille, Cedex 2, France

Fossiliferous lacustrine deposits of middle Pleistocene age have been found in Central Fezzan (Libya)¹ on each side of the east–west depressions of the Wadi Shati, south of the Pre-cambrian Qarqaf anticline^{1–8}. They represent the shoreline of a former brackish water lake (Fig. 1) which, some 130,000 yr BP, covered an area about 100 km long and 10–20 km wide. At present, the area may be classified as hyperarid. Since 1978, a collaborative study of the fossil assemblages has been undertaken. It included macro- and micropaleontological determination, Th/U dating, stable isotope and chemical analyses, in parallel with sedimentological and archaeological studies of the sites. Here we consider the Th/U dating and the isotopic palaeohydrology of the lacustrine episode.

Two main facies have been observed. The first and most extensive occurs in the main central and western depressions of the Shati. It consists of isolated outcrops, 2–8 m in height and 5–15 m in diameter. They are almost totally composed of layers of mollusc shells, cross-shells, broken or whole shells, sometimes with both valves joined, with a variable but small amount of quartz sand. Typical current orientations of pelecypod valves are observed, which, in conjunction with the abundance of fragments, indicate a littoral environment. These deposits occur at elevations 330–347 m, some 40–60 m above the bottom of the Shati depression. They represent a single major lacustrine episode with large lake-level fluctuations (~10–15 m), as suggested by the alternance of topsets and bottomsets.

The second facies occurs in two small and partly isolated depressions at the eastern margin of the Shati Valley. It consists of quartz sands containing small pebbles which originate from the Nubian sandstones (Lower or Mid-Cretaceous continental deposits). Scattered shells or small layers of shells are present here and there. The easternmost depression reveals freshwater molluscs; the intermediate one shows both fresh- and brackish-water fauna. Fluvial inputs characterize this margin of the lake, where freshwater fauna developed in small embayments. Note that these depressions could have been partly filled with water during several episodes after the main lacustrine phase.

In the main lake, the fauna includes molluscs³, ostracods⁵ and foraminifera⁵. Among the molluscs, *Cerastoderma glaucum*, the Mediterranean cardium, is by far the most abundant species. It is usually associated with *Melania tuberculata* and *Hydrobia* sp. This fossil assemblage reflects a shallow water community (depth <10 m) living on a sandy substrate³. It also suggests a temperature of ~20 °C (which is implied for larval development of cardium) and a minimum salinity³ of 3‰. In contrast, the deposits in the small depressions of the eastern margin are

Fig. 1 Proposed area for the Shati Cardium Lake, .

characterized by freshwater assemblages which include *Corbicula africana*, *Coelatura lacoini*, *Bulinus truncatus* and *Limnaea natalensis*.

The shell morphology of *Cyprideis*, which is the only occurring genus of ostracods, indicates a strongly variable physical environment. The salinity ranged from 5 to 10‰ during the periods of *Cyprideis* development^{8,9}.

Surprisingly, five species of marine foraminifera have been identified in these lacustrine sediments which are located almost

1,000 km from the sea: *Ammonia beccarii tepida*, *Protelphidium paraliu*, *Criboelphidium articulatum*, *Discorbis* sp. and *Rosalina globularis*⁵. Such occurrences, so far inland, of marine organisms in saline lakes are probably due to transportation by migrating birds. From a palaeoecological point of view, the Shati Cardium Lake fossil assemblages reflect brackish but highly variable conditions. Charophytes (*Lamprothamnium* sp.) also occur at a few localities^{10,11}; they could correspond to a 5–10‰ salinity range¹² in agreement with the ostracod requirements.

Stable carbon and oxygen isotope analyses have been made on 46 samples of fossil shells and calcitic cement. For each sample, Mg^{2+} , Sr^{2+} contents and calcite/aragonite ratios have been determined. As Fig. 2 shows, some shells present high $\delta_{PDB}^{18}O$ and $\delta_{PDB}^{13}C$ values that are almost characteristic of 'marine' conditions. The Cardium Lake seems to be a perfect example of isotopic fractionation in a closed basin, where evaporation induces an increase of ^{18}O and ^{13}C content in the water phase¹⁴. A direct $\delta^{18}O$ salinity relationship cannot be established as the original ionic concentrations are unknown. The samples from the eastern part of the lake show typical freshwater conditions with lower $\delta^{18}O$ and ^{13}C values. Therefore, one may assume that the strongest freshwater inputs came from the east. In general, isotope ratios of the shells reflect brackish but highly variable conditions. Many samples present clear evidence of recrystallization. They are characterized by low $\delta^{18}O$ values and high ^{13}C content, almost identical to the values which are observed in the calcite which cements the shells. Calcite/aragonite ratios systematically confirm this interpretation. Moreover, lower Sr^{2+} and higher Mg^{2+} content may be observed in these recrystallized shells. The isotopic shift which occurs during aragonite–calcite transformation could thus determine the stability or originally calcitic shells. Hence, it is possible to use such calcitic shells for Th/U dating, as the ^{18}O and ^{13}C content reflects the mineral stability and the risk of contamination. In the Cardium Lake fossils, the large ^{18}O variations due to evaporation totally erase the temperature effect, the amplitude of which is much less.

More than 20 Th/U dates have been obtained on the cardium shells, by the ionium disequilibrium method¹⁵, with systematic X-ray control of calcite occurrence in the originally aragonitic shells. Most of the dated samples presented a negligible percentage of calcite—only occasionally does the calcite/aragonite ratio exceed 0.1. But even then, the ages seem to

Fig. 2 Carbon and oxygen isotopes of the Shati Cardium Lake fossils. Three groups are indicated: 1, freshwater conditions; 2, brackish water conditions; and 3, fossils with aragonite–calcite transformation. ●, Fossils; ■, calcitic cement.

Fig. 3 Frequency histogram of U/Th dates $\pm 1\sigma$. Total number of dates, 21.

agree with those obtained on purely aragonitic shells. This would indicate a very precocious (almost syngedimentary) phase of aragonite-calcite transformation. Moreover, the ^{238}U content (<1 p.p.m.) between samples is comparable¹⁶. The $^{234}\text{U}/^{238}\text{U}$ ratios are greater than 1.15 and clearly reflect the continental nature of the water⁶. The $^{232}\text{Th}/^{230}\text{Th}$ ratios are very small (few p.p.m.), indicating negligible Th contamination. Figure 3 shows that the major lacustrine episode took place some 130 kyr BP. Although it is difficult to be precise about the duration of this phase, it clearly preceded the 125 kyr climatic optimum of the last (Eemian) interglacial. It seems more realistic to associate it to the transition between Stages 6 and 5e of the oceanic ^{18}O record¹⁷. A few dates averaging around 90 kyr and around 40 kyr suggest two more recent but less extensive humid episodes, with small lakes within some of the depressions.

As in most Saharan sites, the prehistoric artefacts are surface finds, for the greatest part, but in some cases they have been observed *in situ* in the lake deposits. They belong to at least two different cultures. Primarily there are biface tools of middle Pleistocene age, presenting typical late Acheulean features. Second, characteristic Levallois-Mousterian lithics are also present. These archaeological periods seem to fit the lake chronology.

From a palaeoclimatic point of view, the major phase of the Shati Cardium Lake developed at the end of the middle Pleistocene and as evidenced by sedimentology, stable isotopes and faunal assemblages, was characterized by large fluctuations and considerable evaporation, leading to almost 'marine' conditions. It seems realistic to associate these fluctuations mainly with groundwater oscillations.

We thank Professor Rhodes W. Fairbridge for helpful comments.

Microbiological and zooplankton activity at a front in Liverpool Bay

G. D. Floodgate, G. E. Fogg, D. A. Jones, K. Lochte & C. M. Turley

Department of Marine Biology, Marine Science Laboratories (University College of North Wales), Menai Bridge, Gwynedd LL59 5EH, UK

Shallow sea fronts, zones of transition between mixed and stratified waters, are generally characterized by accumulation of biomass^{1,2}. Various mechanisms can be suggested for this accumulation. Pingree *et al.*¹ considered that phytoplankton are limited on the stratified side by nutrient supply and on the mixed side by light intensity, whereas at the front itself, recently stabilized mixed water provides conditions for rapid growth. Adjacent water masses may also complement each other's nutrient deficiencies. At the western Irish Sea front for example, silica has been limiting on the mixed side and combined nitrogen on the stratified side, so that the front supported more algal growth than either water separately². Another possibility, as fronts are regions of convergence, is advection of suspended matter, which may include detritus, phytoplankton and zooplankton³. This is unlikely to end with the passive accumulation of material at the front: bacterial mineralization of organic detritus will stimulate phytoplankton growth, bacterial and phytoplankton growth will support increased zooplankton activity and this in turn will increase the rate of recycling. Although little investigated, this mechanism seems to be important in a front existing in Liverpool Bay, as we report here.

Fig. 1 Position of the Liverpool Bay and western and south-western Irish Sea fronts. Position of anchor station (A6) and station positions along reference line are indicated.

The general hydrographic and chemical features of Liverpool Bay have been described by Foster *et al.*⁴. A discontinuity or front, running approximately due north along the 4°W line of longitude from Great Orme Head, is a fairly regular feature in the Bay. In winter this front depends largely on salinity differences arising from river inflow whereas in summer, surface heating plays the major part in maintaining it. A study completed since the observations reported here shows that the situation is complex and that stratification associated with the front only becomes established in calm weather (S. Czitrom, unpublished results). The intermittent nature of this front undoubtedly complicates the biological picture and, for this reason, further investigation of bacterial and zooplankton activities at fronts is being conducted on the more stable western Irish Sea front (Fig. 1).

Observations were made along a transect at right angles to the Liverpool Bay front, which formed part of a grid of stations regularly occupied for hydrographical and phytoplankton surveys by R. V. Prince Madog (Fig. 1). Station positions were corrected to refer to the same tidal phase. Surface temperature and salinity were recorded continuously; at each station and half-way between regular stations, vertical profiles of temperature and salinity were determined (S. Czitrom, unpublished results). Microbiological samples were taken with sterile 2.5-l glass bottles attached to Johnson-Zobell microbiological samplers. Total bacterial numbers were estimated by an acridine orange epifluorescence direct counting technique⁵⁻⁷. Bacteria were classified into four size classes and volumes calculated by approximating to regular geometric shapes with ranges of volumes as follows: 'mini-bacteria' (cocci and rods) 0.004–0.1 μm^3 , cocci 0.1–0.4 μm^3 , rods 0.03–0.2 μm^3 and large rods

Fig. 2 Distribution of *a*, stability factor, $\bar{V}$ (○) and surface density, σ_t (×); *b*, bacterial (○) and phytoplankton (●) biomass in surface water; and *c*, bacterial mean cell volume (○) in surface water along the reference line indicated in Fig. 1 on 13–14 February 1978. $\bar{V}$ is the energy input required per unit depth to bring about complete vertical mixing of the stratified water column.

Fig. 3 Distribution of *a*, stability factor $\bar{V}$ (○, see Fig. 2 legend) and surface density, σ_t (×); *b*, bacterial (○) and phytoplankton (●) biomass, microbial cellular ATP (□) and cellular ATP/carbon ratios (×); and *c*, bacterial mean cell volume (○) in surface waters along the reference line indicated in Fig. 1 on 5 June 1978.

0.2–0.7 μm^3 . ATP content was determined according to Holm-Hansen and Booth⁸ and chlorophyll *a* content according to Yentsch and Menzel⁹. Bacterial biomass was calculated in terms of carbon from total bacterial volume assuming a density of 1.1 g cm^{-3} , a dry/wet ratio of 0.2 and a carbon/dry weight ratio of 0.5 (refs 10, 11). Phytoplankton biomass was calculated in terms of carbon using an organic carbon/chlorophyll *a* ratio of 30 (ref. 12). Zooplankton samples were obtained by surface tows and vertical hauls made through the whole water column.

In the late winter the vertical distribution of density (σ_t) along the transect showed mixed water offshore and stratified water inshore with the front near station 14, a situation clearly related to the high inflow of fresh water into the Bay during the winter. A similar picture of bacterial distribution, shown in Fig. 2, emerged from all four surveys made in winter/early spring. Bacterial biomass showed a peak on the inshore side of the front, the position of which was clearly defined by steep gradients in density and stability factor $\bar{V}$ (ref. 13). Bacterial biomass, in fact, correlates positively with $\bar{V}$ when stratification occurs. There was also a consistent difference in distribution of the size classes of bacteria, with the minibacteria predominating offshore, and the larger forms inshore, of the front. Bacterial biomass was always in considerable excess of phytoplankton biomass, which showed low levels without obvious relation to the front. In late spring/early summer the picture changed and in four surveys during this period was as shown in Fig. 3. Bacterial biomass was low, without any major difference on the two sides of the front. There was, however, the same pattern in size distribution as was

found earlier in the year. Phytoplankton biomass now greatly overshadowed bacterial biomass and was greatest adjacent to the front on the stratified side, a distribution similar to that found by Pingree *et al.*¹ at the front in the approaches to the English Channel. ATP concentration generally followed phytoplankton concentration but was higher than expected at the front itself, where there was a peak in microbial ATP/cellular carbon ratio.

When mean values for chlorophyll, bacterial numbers and ATP/cellular carbon ratio in the water column were plotted for the different stations as a function of time, the higher values for both chlorophyll and bacterial numbers were seen to have been always on the landward side of the transect. Bacterial numbers were highest in early spring and chlorophyll concentration was greatest in late spring and early summer with the ATP/cellular carbon ratio reaching a peak in between. The mean cell volume of the bacteria also increased with time to reach a peak at the same time as the chlorophyll.

Evidence that microbial activity as distinct from biomass was high at the front was provided by studies of urea utilization. These were made by determining release of $^{14}\text{CO}_2$ (measured as $^{14}\text{CO}_2$ released on acidification plus particulate ^{14}C) from ^{14}C -urea added to samples incubated on deck in the light (700 lx) and in the dark at 21 °C. Both phototrophic and heterotrophic breakdown of urea per unit volume of water, which were positively correlated, occurred at rates three to four times higher at the front than away from it (Fig. 4). Urea is metabolized by both bacteria and algae and evidence presented by Butler *et al.*¹⁴ indicates that urea, among other nitrogenous organic substances, may also be an important source of nitrogen for some phytoplankton species. Urea concentrations, measured by the method of McCarthy¹⁵, were highest at the front ($\sim 1 \mu\text{g l}^{-1}$ at 5 and 10 h in the series of observations shown in Fig. 4, compared with $\sim 0.1 \mu\text{g l}^{-1}$ at other times). Urea in offshore

Fig. 5 Distribution of adult and juvenile copepods along the reference line indicated in Fig. 1 during *a*, March 1978; *b*, May 1978; and *c*, July 1978.

waters is not derived from discharges from the land but seems to be produced *in situ*, possibly by zooplankton (Turley, unpublished results)—in accordance with this, zooplankton were found to be concentrated at the front. Surveys in March, May and July 1978 found that total numbers of zooplankton at the front were between two and eight times higher than at stations on either side. Not only were there greater numbers of zooplankton but zooplankton development seems to have been more advanced at the front than elsewhere. When copepod distribution was examined, juveniles were found to reach a peak in this position in March and May whereas in July the peak was largely formed by adults (Fig. 5). This requires substantiation but we believe that breeding of copepods at the front is about 30 days in advance of the norm elsewhere in Liverpool Bay.

Thus, our results, which will be reported in more detail elsewhere, point to the activities of the various living components advected into a front being mutually accelerating. The greater numbers of bacteria inshore and in the winter suggest that they are mainly dependent on particulate and dissolved organic matter brought in by land run-off and these high populations seem from microscopical observations to be associated with particulate matter. Novitsky and Morita^{16,17} have related small cell size in a marine *Vibrio* to starvation conditions: both greater bacterial size and high ATP/cellular carbon ratios might therefore indicate that supply of bacterial nutrients is greater inshore and at the front than offshore. The increased concentrations of urea and greater urea breakdown associated with the front are in agreement with this. Any tendency for bacterial activity to increase in parallel with liberation of extracellular products by phytoplankton, as observed by Herbland¹⁸ in upwelling waters, is presumably masked by effects of terrigenous organic material, but the coincidence of peaks in both heterotrophic and phototrophic breakdown of urea in May (Fig. 4) suggests that intensification of bacterial activity occurs at

the front when there is a large phytoplankton population. It may also be significant that the mean bacterial size was greatest during the phytoplankton bloom. The high ATP/cellular carbon ratios at the time of transition from the bacteria to algal-dominated state, suggest that the microbial population was then in a particularly active state of catabolism¹⁹.

Zooplankton may be advected into the front and may also actively congregate there but then, because of the abundance of food, first in the form of particulate matter and bacteria and later in the form of phytoplankton, show accelerated development. Zooplankton grazing and excretion would in turn be expected to enhance the rate of recycling at the front.

We thank Drs C. P. Spencer, P. Foster and J. Simpson for advice on the chemistry and physical oceanography of fronts, Mr S. Czitrom for permission to quote his unpublished observations, Dr J. Beardall for the chlorophyll determinations, Mr T. Kendaris and Mr S. O. V. Scrope-Howe for assistance with the zooplankton work, and the officers and crew of R.V. Prince Madog for help. This work was in part supported by grant no. GR3/3091 from the NERC.

Two distinct mechanisms of fibroblast adhesion

P. A. Harper* & R. L. Juliano†

* Department of Medical Biophysics, University of Toronto, Toronto, Ontario, Canada M5S 1A1

† Department of Pharmacology, University of Texas Medical School at Houston, PO Box 20708, Houston, Texas 77025, USA

The adhesion of cells to the connective tissue matrix is commonly thought to be governed by fibronectin, a pericellular glycoprotein with binding sites for cell surfaces, collagen and glycosaminoglycans. Here we report evidence that Chinese hamster ovary (CHO) cells possess an alternative mechanism for adhesion which is independent of fibronectin. Cells of a variant CHO clone called AD^F11 are defective in their ability to adhere to fibronectin-coated substrata, but can adhere to a substratum coated with SAM (substrate-attached material), a pericellular material produced by fibroblasts. The adhesion of wild-type CHO cells to fibronectin-coated substrata and adhesion of AD^F11 cells to SAM-coated substrata are differentially sensitive to proteolytic treatment. This suggests that there are two distinct adhesion mechanisms for CHO cells, only one of which is dependent on fibronectin.

† To whom correspondence should be addressed.

Fig. 1 Adhesion of WT and AD^F11 cells to SAM- and serum-coated substrata. The preparation of SAM- and serum-coated substrata, and the adhesion assay have been described elsewhere¹⁶. Aliquots of ³H-labelled suspension-adapted WT or AD^F11 cells were added to dishes coated with SAM or serum substrata and incubated at 37 °C and 5% CO₂. At various times, the dishes were removed from the incubator, washed extensively with PBS, pH 7.2, thus removing the non-attached cells and the fraction of radioactivity remaining on the plate due to the attached cells was determined. *a*: □, WT cells on serum; ■, WT cells on SAM. *b*: ○, AD^F11 cells on serum; ●, AD^F11 cells on SAM. Each point represents the mean of three determinations. The SAM used in these experiments was prepared from confluent human diploid fibroblasts as described elsewhere^{16,19}.

Variations in the capacity of a cell to make and break adhesive connections with other cells and with the extracellular matrix have been implicated in a number of important biological processes including organogenesis, wound healing and the invasive and metastatic behaviour of tumour cells¹. Recent studies of cell adhesion have focused on the role of the fibronectins, which are high molecular-weight glycoproteins found on cell surfaces, in the interstitial matrix and in plasma^{2,3}. Fibronectins can interact with the cell surface and with several types of macromolecules including collagen⁴⁻⁹, glycosaminoglycans^{10,11}, fibrin¹² and possibly glycolipids¹³; the binding properties of fibronectin, together with its pericellular location, suggest that this molecule provides an adhesive link between the cell surface and the extracellular matrix. Both the plasma and cellular forms of fibronectin can promote the adhesion and spreading of a number of transformed fibroblast cell lines on collagen-coated surfaces¹⁴, while cellular fibronectin can also restore a more 'normal' morphology to transformed fibroblasts¹⁵. It seems evident therefore, that the fibronectin-collagen complex is important in fibroblast adhesion. However, the possibility that macromolecular or cellular systems other than fibronectin may also be involved in adhesion has not been extensively explored. Here we present evidence for an alternative mechanism of cell adhesion independent of fibronectin.

As a tool for studying mechanisms of cell adhesion, we recently isolated and characterized a series of CHO cell variants (AD^F (adhesion variant) cells) which are markedly defective in their ability to adhere to fibronectin-coated collagen¹⁶; these cells also fail to adhere to serum-coated surfaces, as fibronectin is the major adhesion-promoting molecule in serum. Although AD^F cells have lost the ability to adhere to a fibronectin-coated substratum, these cells can attach and spread normally on

Fig. 2 Micrographs of WT and AD^vF11 on SAM- and serum-coated substrata. Dishes pre-coated with SAM or serum were prepared as described in Fig. 1 legend. Aliquots of AD^vF11 or WT cells were added to the pre-coated dishes and incubated at 37 °C and 5% CO₂. After 90 min the dishes were washed with PBS and the remaining attached cells were fixed with 0.1% glutaraldehyde in PBS. The cells were observed by phase contrast photomicroscopy. *a*, WT cells on serum; *b*, AD^vF11 cells on serum; *c*, WT cells on SAM; *d*, AD^vF11 cells on SAM.

substrata coated with other ligands which are capable of forming multivalent attachments to cell surfaces (for example, concanavalin A, polylysine). In addition, we found that AD^v cells can attach and spread on substrata coated with SAM, a pericellular substratum-attached material which is derived from fibroblasts and which has been reported to enhance the adhesion of some types of cells¹⁷.

When fibroblasts are removed from a substratum by treatment with chelating agents such as EGTA, a pericellular material is left on the surface. This material, known as SAM or 'footpads' is a complex mixture of macromolecules including proteins (fibronectin and actin are two prominent components)¹⁸, glycosaminoglycans and phospholipids^{19,20}, and is organized into small vesicular structures surrounded by amorphous or fibrous deposits^{21,22}. AD^v cells can adhere and spread on SAM-coated substrata, presumably because the cells can bind to one or more of the macromolecules in the SAM complex. We demonstrate that the adhesion of wild-type (WT) CHO cells to fibronectin-coated substrata and the adhesion of AD^v CHO cells to SAM-coated substrata are mediated by different mechanisms, which suggests that there are two separate systems for cell adhesion.

The adhesion behaviour of WT and AD^v cells on SAM-coated substrata and on serum-coated substrata is shown in Fig. 1. WT cells adhered rapidly and extensively (80–95%) to both types of substrata; by contrast clone AD^vF11 cells adhered readily (80%) to SAM-coated substrata, but failed to adhere (<3%) to serum-coated substrata. Figure 2 shows that the WT cells which attached to SAM- or serum-coated substrata went on to spread and assumed similar morphologies on the two surfaces. AD^vF11 also spread and attained a fairly normal CHO cell morphology on SAM substrata.

Treatment of SAM with several perturbing agents (Table 1*a*) did not impair its suitability as an adhesive substratum for WT and AD^vF11 cells; SAM treated with the non-ionic detergent Triton X-100 (TX-100), with chondroitinase ABC or with 4 M urea sustained cell adhesion as well as control SAM substrata. In these experiments >85% of sulphated glycosaminoglycans

Table 1 Perturbation of adhesion to SAM

<i>a. Treatment of SAM</i>		TX-100 (0.1%)	Ch ABC (0.5 U ml ⁻¹)	Thrombin (10 U ml ⁻¹)
Clone	Control			
WT	100	95.2 ± 5.9	98.6 ± 4.6	99.7 ± 3.0
AD ^v F11	100	94.2 ± 16.4	98.3 ± 1.5	97.5 ± 1.5
		Urea (4M)	Trypsin (5 µg ml ⁻¹)	
Clone	Control			
WT	100	99.8 ± 9.8	42.2 ± 8.6	
AD ^v F11	100	98.9 ± 10.0	12.5 ± 4.5	
<i>b. Treatment of cells</i>		Thrombin (10 U ml ⁻¹)	Trypsin (5 µg ml ⁻¹)	
Clone	Control			
WT	100	91.3 ± 14.1	100.6 ± 4.6	
AD ^v F11	100	65.7 ± 6.8	12.4 ± 3.3	

Effects of various agents on the adhesion of AD^vF11 and WT cells to SAM substrata. Substrates pre-coated with SAM were prepared as described in Fig. 1 except that, on removal of the detached fibroblasts, the dishes were further extracted with various agents. Thus dishes were incubated with 0.5 U ml⁻¹ chondroitinase ABC (Ch ABC, Miles) or 10 U ml⁻¹ thrombin (Sigma) in adhesion buffer, with 4 M urea or with 0.1% TX-100 in phosphate-buffered saline (PBS), pH 7.2, all for 40 min at 37 °C, or with 5 µg ml⁻¹ crystalline trypsin in PBS for 10 min at room temperature. After extraction, the dishes were washed with PBS and the attachment of WT and AD^vF11 after 90 min was determined as described in Fig. 1 legend. The data are expressed as the per cent of cells attached to treated plates against per cent attached to control SAM plates treated only with adhesion buffer. To evaluate the extent of the extraction procedures, SAM substrata derived from fibroblasts incubated with 10 µCi ml⁻¹ ³⁵S-sulphate to label GAGs, 10 µCi ml⁻¹ ³H-leucine to label proteins, or with 10 µCi ml⁻¹ ³H-oleic acid to label phospholipid, were similarly extracted and the fraction of radioactivity remaining on the plate determined (data in text). The data represent the mean and standard error of at least three experiments, each comprised of three or more determinations. Note that the SAM substrata probably also contain regions where the tissue culture dish is coated with serum, as the fibroblasts which produce SAM were originally grown in medium containing serum. Adhesion buffer comprised alpha MEM with 1 mg ml⁻¹ bovine albumin.

Fig. 3 The adhesion of trypsin-treated WT and ADⁱ cells to SAM- or serum-coated substrata. Suspension-adapted ³H-labelled WT or ADⁱF11 cells were treated with various concentrations of trypsin in PBS for 10 min at room temperature. Digestion was stopped by the addition of 50 volumes of ice-cold adhesion buffer containing 5 mg ml⁻¹ BSA followed by extensive washing of the cells; the cells were then assayed for their ability to attach to substrata coated with SAM or serum as described in Fig. 1 legend. To avoid the possibility of re-synthesis of surface components²³, the adhesion assay was limited to 30 min at 37 °C—sufficient time for the adhesion process to near completion. ◇, Trypsinized WT cells on serum substrata; ○, trypsinized ADⁱF11 cells on SAM substrata. Each point represents the mean of at least three determinations.

(GAGs) in SAM were removed by treatment with TX-100, chondroitinase ABC or 4 M urea; >75% of protein in SAM was removed by TX-100 or 4 M urea; >95% of the phospholipid was removed by TX-100; otherwise removal of GAG, protein and lipid was <25%. By contrast, treatment of SAM with low doses of trypsin (which removed ~75% of SAM protein) caused a marked reduction in its ability to support cell adhesion. In further experiments (Table 1b), treatment of ADⁱF11 cells with

thrombin or with low doses of trypsin markedly inhibited cell adhesion to SAM; by contrast WT adhesion to either SAM- or serum-coated substrata was unaffected by equivalent protease treatments of these cells.

These results suggest that ADⁱ cell attachment to SAM might be mediated by an interaction between cell-surface proteins and protein components in SAM. In addition, WT adhesion to serum-coated substrata and ADⁱ cell adhesion to SAM substrata might involve different cell components and mechanisms. This was confirmed by the experiments shown in Figs 3 and 4. Figure 3 shows that the cell-surface components involved in attachment of ADⁱ cells to SAM substrata were far more trypsin sensitive than the surface components involved in WT attachment to serum-coated substrata. The concentration of trypsin required to reduce adhesion of WT to serum substrata by 50% was 200 µg ml⁻¹, but only 2 µg ml⁻¹ for ADⁱ adhesion to SAM substrata.

The role of fibronectin in the adhesion of WT and ADⁱ cells was also evaluated using an anti-fibronectin antibody (Fig. 4). After treatment of the substratum with antibody, WT cells failed to adhere to fibronectin-coated collagen. However, antibody treatment of the SAM substratum did not impair the adhesion of WT or ADⁱF11 cells. Because the antibody effectively blocked fibronectin-mediated adhesion, its failure to block attachment to SAM implies that fibronectin is not directly involved in this process.

These results suggest the existence of two distinct mechanisms for adhesion in CHO cells, the first of which involves an association between fibronectin on the substratum and cell-surface components which are relatively trypsin resistant²³—this mechanism is utilized in WT CHO attachment to fibronectin-coated substrata. The second mechanism involves an association between trypsin-sensitive surface components and one or more substratum attached macromolecules other than fibronectin—this mechanism is used in ADⁱF11 attachment to SAM-coated substrata. It is likely that both mechanisms operate in WT cells, but that ADⁱ cells lack the fibronectin mediated mechanism. It seems premature at this stage to decide on the precise identity of the molecules involved in ADⁱ cell attachment to SAM. The results given in Table 1 and Fig. 4 suggest that neither GAGs nor fibronectin are involved; the possible involvement of fibroblast-secreted collagen or of other SAM components remains to be determined.

The authors thank Dr R. Rajaraman for the rabbit anti-human CIG. This work was supported by a grant from the NSF, and was carried out as part of a PhD thesis in the University of Toronto.

Fig. 4 Effect of anti-fibronectin antibody on adhesion. SAM-coated substrata were prepared as described in Fig. 1 legend. Collagen substrata (gelatinized rat-tail tendon collagen) were prepared as described elsewhere¹⁶ and were coated with 200 µg ml⁻¹ affinity-purified human serum fibronectin (CIG)²⁴. Both types of substrata were incubated in PBS with or without rabbit anti-human CIG diluted 1:10 for 90 min at room temperature. Thereafter the substrata were rinsed extensively with PBS and the adhesion of WT or ADⁱF11 cells during a 90-min period at 37 °C was measured, as described in Fig. 1 legend. Data represent the mean of three determinations. The data are normalized, based on the adhesion of WT cells to fibronectin-coated collagen (no antibody treatment) as 100%. *a*, Fibronectin-coated collagen substratum; *b*, SAM substratum. +, Pretreated with anti-fibronectin antibody; —, untreated.

Functional asymmetries between the two sides of the brain, a well documented phenomenon in species as different as frog and man^{1,2}, are thought to arise from genetically determined anatomical differences which, at least in humans, may be observed *in utero*³. Functional asymmetries can, however, be reversed after damage to one side of the brain⁴. Here we report that rearing of kittens with the optic chiasm sectioned and one eyelid sutured during postnatal development results in a functional asymmetry in the corpus callosum, a bidirectional pathway which inter-connects the visual cortices on the two sides of the brain. Visual input originating on the side of the brain ipsilateral to the sutured eye loses the ability to influence cells on the other side of the brain. Conversely, visual input originating on the side of the brain ipsilateral to the exposed eye markedly increases its influence in the other hemisphere.

Fig. 1 *a*, General organization of the visual system in frontal-eyed mammals. Nerve fibres leave each eye and meet at the optic chiasm where fibres from the nasal hemi-retinae cross to the other side of the brain and those from the temporal hemi-retinae remain on the same side. Retinal inputs terminate in the LGN from where fibres project to the ipsilateral visual cortex. The corpus callosum inter-connects the visual cortices on the two sides of the brain. In the split-chiasm cats whose ocular dominance distribution is shown in *b*, the optic chiasm was subjected to midsagittal section when the animals were adults. This interrupts retinal input to the opposite side of the brain but leaves ipsilateral input intact. The abscissa of the ocular dominance distribution represents the relative excitatory contribution of the two eyes with increasing influence of the ipsilateral eye represented by successively higher numbers on a scale from 1 to 7 (ref. 16). The ordinate represents the number of cells encountered in each ocular dominance group. Most cells are more strongly influenced by stimulation of the ipsilateral eye in these cats, but many cells receive at least some input from the contralateral eye via the callosal pathway shown in *a*. *c*, 'Deprived hemisphere'. *d*, 'Exposed hemisphere': the ocular dominance distribution on the two sides of the brain in kittens in which the left eyelid was sutured at the same time as the chiasm was sectioned. In the hemisphere ipsilateral to the exposed eye all cells encountered were influenced solely by the exposed eye. In the other visual cortex, ipsilateral to the deprived eye, most cells received their major input from the eye on the opposite side of the brain despite the chiasm section.

The preparation used is shown in Fig. 1*a*. Four kittens were reared normally from birth until 21 days of age, when they were subjected to surgical section of the optic chiasm and at the same time the left eyelid was sutured^{5,6}. The kittens then received visual exposure in a normally lit environment until they were 4 months old. Optic chiasm section restricts visual input from one eye to one hemisphere by severing optic nerve fibres which cross to the opposite side of the brain. Suturing of the left eyelid prevents visual input from reaching the left visual cortex via the direct ipsilateral pathway through the lateral geniculate nucleus (LGN). The only route by which visual input can reach the left visual cortex in these kittens is a pathway from the right eye through the right LGN and visual cortex, then across the corpus callosum to the left visual cortex.

To compare the effectiveness of the direct visual route via the LGN with the indirect pathway described above in normally reared animals, we sectioned the optic chiasm in three adult cats and then recorded the visual responses of single cells at the border of cortical areas 17 and 18, where the corpus callosum is known to terminate⁷⁻⁹, using conventional methods described elsewhere¹⁰. The distribution of ocular dominance for cortical units found in these cats is shown in Fig. 1*b*, where the abscissa, numbered from one to seven, represents the relative excitatory input from each eye. After chiasm section in adult cats, most of the units encountered receive stronger input from the ipsilateral eye than the contralateral eye, indicating that the direct route

outlined above is more effective than the indirect pathway via the corpus callosum^{6,11}. Over 80% of the units encountered could however, be driven, to some extent, by stimulation of either eye. Despite the fact that the receptive field properties for the two eyes were determined by thalamic and callosal input respectively, visual response characteristics such as orientation, direction, and velocity selectivity were similar for a given neurone, regardless of which eye was stimulated. When one hemisphere was inactivated in these split-chiasm cats, all visual input to the remaining hemisphere was from the ipsilateral eye^{6,11}, which supports anatomical findings that the contralateral eye input reaches the cortex via the indirect route outlined above.

We recorded visual responses of single cells from the visual cortex on both sides of the brain in the four kittens in which one eyelid was sutured at the same time as chiasm section was performed. Multiple penetrations made oblique to the cortical surface ensured that a wide region of cortex near the 17/18 border was explored. The results are shown in Fig. 1d. On the side of the brain ipsilateral to the nonsutured eye, the 'exposed hemisphere', all units encountered were driven exclusively via stimulation of the exposed eye. No units were driven through the eye which had been sutured until the recording session began—this indicates a functional loss of input originating from the other side of the brain in these animals and mimics the situation in which that hemisphere is inactivated^{6,11}. Recording from the side of the brain ipsilateral to the previously deprived eye in these same kittens ('deprived hemisphere', Fig. 1c), we found that the effectiveness of input originating via the contralateral (exposed) eye was greatly enhanced relative to that found in adult split-chiasm cats. Inputs from this eye were clearly more effective than inputs from the deprived eye in driving most cortical cells. This indicates a substantial increase in the effectiveness of inputs originating on the side of the brain receiving visual stimulation during development relative to those from the deprived eye.

Our results show that the functional effectiveness of callosal connections can be markedly enhanced or diminished on different sides of the same brain. In effect, the corpus callosum has been transformed from a bidirectional pathway into a one-way route. Information originating in the 'exposed' hemisphere flows to the 'deprived' hemisphere but not in the reverse direction. These physiological findings are supported by the results of anatomical studies which show that the terminal field of the corpus callosum is markedly expanded in the 'deprived' hemisphere relative to the 'exposed' hemisphere¹². This induced functional asymmetry shows that the postnatal exposure history of the animal can modify the effectiveness of cortical output pathways in a similar manner to that by which it alters the effectiveness of inputs to the cortex¹³⁻¹⁵.

High-frequency transformation of the fission yeast *Schizosaccharomyces pombe*

David Beach & Paul Nurse

Biochemistry Laboratory and Genetics Group, University of Sussex, Brighton, Sussex BN1 9QG, UK

The fission yeast, *Schizosaccharomyces pombe*, has been used extensively for genetic studies but until now it has not been utilized as a host organism for DNA cloning. Here we describe a method for high-frequency transformation of a *leu*⁻ strain of this yeast with hybrid plasmids containing the *Saccharomyces cerevisiae* *LEU*²⁺ gene, a bacterial plasmid and either the *S. cerevisiae* 2 μ m plasmid or autonomously replicating sequences (*ars*)¹ derived from *S. pombe* DNA. Some of the plasmids contain unique restriction sites which make them suitable for the isolation of *S. pombe* genes, and they can also be used for the exchange of DNA between *S. pombe* and *S. cerevisiae*.

The plasmid, pJDB248, incorporates the *S. cerevisiae* *LEU*²⁺ gene which codes for β -isopropylmalate dehydrogenase, the bacterial plasmid pMB9 and the entire 2 μ m plasmid². It can be propagated in both *Escherichia coli* and *S. cerevisiae*, and transforms the *leu*⁻ *S. cerevisiae* strain MC16 (a leucine auxotroph lacking β -isopropylmalate dehydrogenase), at a frequency of 2×10^4 transformants per μ g DNA. We have tested the ability of this plasmid to transform *leu*⁻ auxotrophic strains of *S. pombe* to *LEU*⁺. Protoplasts were prepared from three strains, *leu* 1.32, *leu* 2.120 and *leu* 3.155. The procedure makes use of an extract of *Trichoderma harzianum*, Novo SP234 (Novo Enzymes), a rich source of 1-3 α glucanases (I. Isenberg, personal communication). Such *Trichoderma* extracts have been shown previously to digest the wall of *S. pombe*, to give protoplasts³. Protoplasts were washed three times in an osmotic buffer, 1.2 M sorbitol, to remove lytic enzymes, and incubated with plasmid DNA in the presence of CaCl₂ and polyethylene glycol essentially as described in ref. 2. After a further period of incubation in a leucine-supplemented medium, the protoplasts were plated directly onto minimal medium with 1.2 M sorbitol without using an agar overlay and incubated at 32°C for 4-5 days. The detailed method is given in Fig. 1 legend.

After this procedure only the *leu* 1.32 protoplasts give rise to colonies at a frequency greater than that of back-mutation. In the conditions used, pJDB248 transforms this strain to *LEU*⁺ at a frequency of 10^4 transformants per μ g DNA and 1 transformant per 10^4 viable regenerated protoplasts. The frequency of back-mutation of this strain is <1 in 10^7 . *S. cerevisiae* transformants of pJDB248 show frequent loss of the plasmid and consequent reversion to a *leu*⁻ phenotype. The stability of a *S. pombe* transformant of pJDB248 was tested and the proportion of *LEU*⁺ cells in a culture grown for 10 generations under selection in unsupplemented minimal medium was found to be 80%, indicating that the *S. pombe* transformants are also unstable. The presence of the plasmid in transformed *leu* 1.32 clones was demonstrated by preparing DNA from lysates of the yeast, and hybridization to a probe of the bacterial component of the plasmid using the Southern procedure⁴ (Fig. 1). Track 7 of the autoradiograph contains DNA from the untransformed *leu* 1.32 strain and shows no detectable hybridization. However, tracks 5 and 6 containing DNA from two separate pJDB248 transformants show hybridizing bands with electrophoretic mobilities corresponding to the supercoiled (rapidly migrating) and open circular or possibly dimeric (slowly migrating) forms of the plasmid.

These experiments show that *S. pombe* can be transformed at high frequency by the plasmid pJDB248, which contains no

S. pombe DNA. They also show that the *S. cerevisiae* *LEU* 2⁺ gene is expressed in *S. pombe* and that the *S. pombe* *LEU* 1⁺ gene must code for β -isopropylmalate dehydrogenase. In addition, the *S. cerevisiae* 2 μ m plasmid is probably capable of autonomous replication in *S. pombe*, as it is this part of pJDB248 which is likely to be responsible for plasmid replication. However, not all hybrid plasmids containing the 2 μ m plasmid and the *LEU* 2⁺ gene, and able to replicate in *S. cerevisiae*, can transform *S. pombe* at high frequency. An example is pJDB207 which contains only the 2.1-kilobase *Eco*RI fragment of the B form of the 2 μ m plasmid, and which transforms 2 μ m⁺ strains of *S. cerevisiae* at high frequency and has a high copy number (J. Beggs, personal communication). This plasmid transforms *S. pombe* *leu* 1.32 at low frequency (~20 transformants per μ g

Fig. 1 Autoradiograph of ³²P-labelled pAC184 hybridized to a Southern transfer of undigested DNA of yeast transformants. Tracks 1 and 2, transformants of pDamP₄; tracks 3 and 4, transformants of pDamP₂; tracks 5 and 6, transformants of pJDB248; track 7, untransformed host strain. Cells to be transformed were grown to late exponential phase ($1-2 \times 10^7$ cells ml⁻¹) in leucine-supplemented (250 mg l⁻¹) minimal medium⁶. They were collected by centrifugation, washed with 20 mM citrate-phosphate, pH 5.6, and resuspended in the same buffer containing 40 mM EDTA, 0.14 M mercaptoethanol. After incubation at 32 °C for 30 min, the cells were resuspended in 20 mM citrate-phosphate, pH 5.6, containing 1.2 M sorbitol and 5 mg ml⁻¹ SP234 at 32 °C. After 45–60 min by which time protoplasts had formed, the cells were washed three times in 10 mM Tris-HCl, pH 7.6, 1.2 M sorbitol. Cells were resuspended at approximately 5×10^8 cells ml⁻¹ in 10 mM Tris-HCl, pH 7.6, 1.2 M sorbitol, 10 mM CaCl₂ and 10 μ g ml⁻¹ plasmid DNA. After incubation for 15 min at 25 °C, 10 vol of 10 mM Tris pH 7.6, 10 mM⁻ CaCl₂ 20% (w/v) polyethylene glycol 4000 (BDH) were added and incubated for a further 15 min. Finally the protoplasts were pelleted by centrifugation and resuspended at 5×10^7 cells ml⁻¹ in 10 mM Tris, pH 7.6, 10 mM CaCl₂, 5 μ g ml⁻¹ leucine, 0.5 mg ml⁻¹ yeast extract and 1.2 M sorbitol for 30 min at 32 °C. 0.2-ml aliquots (10^7 cells) were plated directly on to 2% agar minimal plates containing 1.2 M sorbitol without using an agar overlay and incubated at 32 °C. The percentage of protoplast regeneration, which was usually ~30%, was estimated using plates supplemented with leucine. Colonies grew up on the plates within 4–5 days. DNA was prepared from yeast by protoplast formation as previously described, followed by lysis in 10 mM Tris-HCl, pH 7.6, 10 mM EDTA, 2% SDS, 100 μ g ml⁻¹ proteinase K at 65 °C. After incubation for 30 min, the lysate was extracted with phenol and precipitated with 0.54 vol of isopropanol in 0.3 M sodium acetate. The precipitate was resuspended in 10 mM Tris-HCl, pH 7.6, 1 mM EDTA. The DNA samples were electrophoresed through a 1% agarose gel and transferred to a nitrocellulose filter⁴. The filter was hybridized with ³²P-pAC184 (500,000 d.p.m.) prepared by nick translation, washed and exposed to Kodak X-OMAT H film with an intensifying screen at -60 °C for several days.

Fig. 2 Plasmid map of pDB248. This plasmid was derived from pJDB248 by partial digestion with *Eco*RI followed by ligation with a complete *Eco*RI digest of pBR322. *E. coli* (JA221) were transformed to *Leu* B⁺ and ampicillin resistance. pDB248 was one such transformant and contains pBR322 and the 4.4-kilobase *Eco*RI fragment of pJDB248. The *Eco*RI sites and unique *Pst*I, *Hind*III, *Bam*HI and *Hpa*I sites are shown. Amp; region coding for ampicillin resistance; Tet, region coding for tetracycline resistance.

DNA), possibly as a result of integration of the plasmid into the chromosome. Also pJDB219 (ref. 2), which contains the full-length 2 μ m plasmid and has a high copy number in *S. cerevisiae*, transforms *S. pombe* at an even lower frequency (~2 transformants per μ g DNA). The reasons for the low frequency of transformation are not apparent.

To have a plasmid capable of high-frequency transformation of *S. pombe* which is suitable for insertion of further genes (for example in the construction of an *S. pombe* gene bank), pJDB248 has been modified. The bacterial pMB9 sequence has been replaced with pBR322, and the 2.3-kilobase *Eco*RI fragment of the 2 μ m plasmid has been removed. The resulting 10.1-kilobase molecule, pDB248, carries both tetracycline and ampicillin resistance, and transforms *S. pombe* with the same frequency as pJDB248. Transformants of pJDB248 and pDB248 also have the same level of instability. pDB248 has unique restriction sites for *Pst*I, *Hind*III, *Bam*HI and *Hpa*I which makes it a suitable cloning vehicle (see Fig. 2).

To extend further the range of potential vectors which can be used to clone DNA in *S. pombe* we tested the transforming ability of eight previously constructed plasmids (pDam Y 1–8)⁵, containing the bacterial plasmid pBR325, the *LEU* 2⁺ gene and fragments of chromosomal DNA from *S. cerevisiae* which promote autonomous replication of plasmids in that yeast. These plasmids transformed *S. pombe* only at low frequency suggesting that these particular *S. cerevisiae* *ars* sequences are not recognized by *S. pombe*. For this reason new plasmids containing *S. pombe* rather than *S. cerevisiae* DNA were constructed by insertion of *Pst*I fragments of *S. pombe* DNA into pDam 1 (pBR325 containing the *LEU* 2⁺ gene). The plasmids were constructed by ligation of *Pst*I-digested pDam 1 (ref. 5), and a partial *Pst*I digest of *S. pombe* DNA. The ligated mixture was used to transform *E. coli* strain JA221 to chloramphenicol resistance. Forty ampicillin-sensitive colonies containing *Pst*I inserts into pDam 1 were picked, and mini-DNA preparations were made and each tested for ability to transform *S. pombe*. Of these 40 plasmids, 9 gave high-frequency transformation of the *leu* 1.32 strain (pDam P_{2–13}). However, the level of transformation obtainable with these plasmids is at least 10-fold lower than that with pJDB248. The transformants are unstable, with the proportion of *LEU*⁺ cells in cultures grown under selection ranging from 35 to 95%, depending on which pDamP

plasmid was present in the transformant. Free copies of the plasmid were also detected in the four transformants tested (Fig. 1). It is not clear whether the size difference of the plasmids obtained from the two independent pDam P₂ transformants (tracks 3 and 4) was the result of plasmid propagation in *E. coli* or *S. pombe*. We conclude that the nine *Pst*I fragments derived from *S. pombe* DNA contain autonomously replicating sequences as previously defined¹. It is uncertain whether these *ars* fragments contain true origins of replication from the *S. pombe* chromosome or are sequences with no chromosomal replicative function, but which happen to be able to 'support' the plasmid in the *S. pombe* cell.

We have described a highly efficient system for transformation of *S. pombe* similar to that developed for *S. cerevisiae*. The plasmid pDB248 contains unique restriction sites which makes it suitable for isolation of *S. pombe* genes. It can also be used to exchange DNA between the two quite different types of yeast. The finding that pJDB248 and pDB248, which contain no *S. pombe* DNA, can replicate in this yeast suggests wide application of the *S. cerevisiae* 2 μ m circle for DNA cloning in other eukaryotic cells.

We thank Melanie Piper and Rachel McIntosh for technical assistance, and Professor S. Shall for laboratory space. The plasmids pJDB248, pJDB207 and pJDB219 were a gift from Jean Beggs, and *leu* strains were supplied by Urs Leupold. We thank Novo for their gift of SP234. This work was supported by the CRC (D.B.) and SRC (P.N.).

Fanconi's anaemia (FA) is an autosomal recessive disorder characterized by a high frequency of 'spontaneous' chromosomal aberrations¹ and an increased risk of cancer². If, as seems plausible, the microscopically visible chromosomal aberrations in this disorder result from DNA or chromatin damage that would normally be repairable, the questions arise as to which step (or steps) in the repair process is deficient and whether the deficiency is intrinsic or the result of secondary factors. We report here that the frequency of chromosomal aberrations in FA lymphocyte cultures is positively related to oxygen tension and suggest that the site primarily affected by the FA mutation is in the complex system of defence (that is, protection and repair) against the genetic toxicity of oxygen.

Whole-blood cultures stimulated by phytohaemagglutinin were incubated for 72 h at various oxygen tensions and screened for chromosomal aberrations. The range of oxygen tensions, 2–50% oxygen, was determined by depression of the mitotic index of both normal and FA cells in more extreme conditions. The frequency of chromosomal aberrations as a function of oxygen tension was found to be markedly different for normal subjects and FA patients.

For normal cells (Fig. 1) the frequency of aberrations was found to be almost constant at a mean of 2 (range 0–4) breaks per 100 metaphases. For FA cells, however, the frequency of aberrations increased dramatically with oxygen tension.

These observations show that FA cells are much more sensitive to cytogenetic oxygen toxicity than normal cells and indicate a role of oxygen in the process leading to chromosomal aberrations. Obvious candidates for oxygen-dependent chromosome damaging agents are the partially reduced ('activated') forms of oxygen, that is, superoxide-free radicals (O_2^-), hydrogen peroxide (H_2O_2), hydroxyl free radicals ($OH\cdot$) and singlet oxygen ($^1O_2$). These 'oxygen radicals' are formed as a result of normal oxygen metabolism³ and could contribute to chromosomal damage in two ways (Fig. 2): (1) by chemical interaction with the chromatin, either directly⁴ or by initiating lipoperoxidation, the products of which could interact with chromatin, resulting in damage⁵; (2) by interfering with DNA repair enzymes, directly⁶ or via lipoperoxidation products⁷.

In normal conditions the above pathways do not lead to alarming levels of microscopically visible chromosomal aberrations because of a cellular defence system consisting of antioxygenic factors (enzymes such as superoxide dismutases, catalase and peroxidases as well as low molecular-weight free-radical scavengers and antioxidants). These prevent excessive accumulation of harmful products of oxygen metabolism and lipoperoxidation and thus protect the genome; the last step of the defence process presumably consists of DNA or chromatin

Fig. 1 Chromosomal aberrations as a function of oxygen tension. Whole blood cultures (0.5 ml heparinized venous blood plus 6 ml Ham F10 medium containing 15% fetal calf serum, phytohaemagglutinin and antibiotics, in glass infusion flasks with a total volume of 45 ml) were gassed with mixtures containing 1% CO_2 and the indicated percentages of oxygen balanced with nitrogen. After 72 h at 37 °C chromosome preparations were made according to an established procedure¹¹. 100 Giemsa-stained metaphases were viewed, on coded slides, for chromosomal aberrations. Metaphases with <40 chromosomes, tetraploids and endoreduplications were not scored. Chromatid and isochromatid breaks were scored as single breaks; dicentric, triradial and quadriradial as two breaks; more complex interchanges as the lowest possible number of breaks required for their reconstruction. Gaps were excluded. Control values, obtained from three individuals on three different occasions, lie within the shaded area. The symbols indicate different (unrelated) FA patients: ● (J.d.W.), a 20-year-old male; □ (P.W.), an 8-year-old male; ○ (R.H.), an 11-year-old male, and + (G.W.), a 10-year-old female.

Fig. 2 Possible pathways in the genetic toxicology of oxygen. O_2^* , activated oxygen species.

repair reactions which remove damage due to products that have slipped through the system. In normal cells, the antioxygenic defence is still able to cope with mildly hyperoxic conditions, whereas in FA cells it seems to fail even in normal culture conditions.

Immunity to *Plasmodium chabaudi adami* in the B-cell-deficient mouse

James L. Grun & William P. Weidanz

Department of Microbiology and Immunology, Hahnemann Medical College and Hospital, Philadelphia, Pennsylvania 19102, USA

Immunity to malaria has a multicomponent basis which requires the participation of both T- and B-lymphocyte systems¹. Previous studies have suggested that the T-lymphocyte system has an essential role in 're-infection immunity' to malaria, but that B cells and/or their products are necessary for the host to survive acute infection and to clear the blood of parasites during chronic malaria^{2–4}. Thus, B-cell-deficient mice and chickens died of fulminant malaria when infected with *Plasmodium yoelii* and *Plasmodium gallinaceum*, respectively^{2,3,5}, but when their acute infections were controlled with subcurative chemotherapy, B-cell-deficient hosts developed chronic low-grade infections and resisted challenge with homologous parasites^{2,4}. In contrast, athymic nude mice failed to control their endogenous *P. yoelii* infection after the termination of drug therapy unless they had been thymus grafted before initiation of acute infection³. We now report that *Plasmodium chabaudi adami* (556KA) infection in B-cell-deficient mice results in an activation of a T-cell-dependent immune mechanism which terminates acute malaria in a similar way to that seen in immunologically intact mice. Furthermore, these immunized B-cell-deficient mice were resistant to homologous challenge infection as well as infections initiated with *Plasmodium vinckei*, but not with *P. yoelii* and *Plasmodium berghei*.

Age- and sex-matched hybrid mice (BALB/c × C57BL/10 and C57BL/6 × CBA) as well as *nu/nu* and *nu/+* mice on a BALB/c background were bred and reared in our animal facilities. Selected litters of mice were rendered B-cell deficient

by lifelong treatment with goat anti-mouse IgM serum (anti- μ) using methods described elsewhere⁴. Anti- μ treated mice, in comparison with immunologically intact mice, had no detectable levels of IgM and were deficient in spleen cells possessing membrane-bound immunoglobulin. B-cell-deficient mice continued to circulate goat anti- μ in their sera for prolonged periods of time and cells from these animals failed to produce specific antibody after immunization with sheep erythrocytes, or dinitrophenol coupled to keyhole limpet haemocyanin. Spleenocytes from treated animals did not respond to the B-cell mitogen lipopolysaccharide, but showed normal responsiveness to the T-cell mitogen, concanavalin A. These mice were as readily sensitized to strong contact allergens, for example, oxazolone and dinitrofluorobenzene, as normal control mice. Prolonged treatment with anti- μ activated macrophages locally within the peritoneal cavity, as shown by enhanced spreading and increased phagocytic activity when these cells were tested *in vitro*. However, there was no systemic activation of macrophages after this treatment because colloidal carbon was cleared from

the blood of treated mice at the same rate as observed in untreated mice (data not shown).

Experimental infections with *P. c. adami* were initiated using a stablate of material originally obtained from D. Wyler (NIH). Mice were infected either intraperitoneally (i.p.) with 10^6 parasitized erythrocytes or intravenously (i.v.) with 10^5 parasitized erythrocytes. Infections were followed by microscopic examination of thin blood films prepared from tail blood and stained with Giemsa stain.

Infections with 10^5 *P. c. adami* produced a bimodal curve of non-fatal parasitaemia in both B-cell-deficient and immunologically intact mice (Fig. 1a). Following the second peak of parasitaemia, B-cell-deficient mice developed chronic low-grade infections as shown by positive blood films. Sub-inoculation of heparinized blood from chronically infected B-cell-deficient mice 50 days after infection to previously uninfected mice produced typical *P. c. adami* infections, indicating that the virulence of the parasites had not been attenuated by passage in the B-cell-deficient host. So far, acute infections with *P. c. adami* in more than 90 B-cell-deficient mice of assorted genotypes have been resolved successfully with no fatalities.

As treatment with anti- μ does not result invariably in immunosuppression^{6,7}, animals in this experiment were evaluated for their immunological competence 45 days after initiation of infection. As shown in Table 1, the sera of B-cell-deficient mice lacked detectable levels of IgM and serum antibodies reactive with *P. c. adami*. In addition, anti-mouse IgM was detected in the sera of all B-cell-deficient mice, demonstrating

Table 2 Specificity of immunity induced by *P. chabaudi* infection in B-cell-deficient mice

Group	No. of animals	Challenge infection	No. resistant No. challenged
A	5	<i>P. chabaudi</i>	5/5*
B	6	<i>P. vinckei</i>	6/6*
C	8	<i>P. berghei</i>	0/8†
D	5	<i>P. yoelii</i>	0/5†

6–8-week old (BALB/c × C57BL/10)F₁ mice were originally infected i.v. with 10^5 *P. chabaudi*-parasitized erythrocytes.

Challenge infections were initiated i.v. with 10^6 parasites 45 d after infection with *P. chabaudi*.

* Parasitaemias in challenged animals did not exceed 0.5%.

† All mice developed fulminant malaria and died within 3 weeks of challenge. Infections in previously uninfected B-cell-deficient mice followed a similar course.

that these animals remained suppressed although they had received intensive antigenic stimulation.

The ability of B-cell-deficient mice to control endogenous parasites was one indicator of immunity, but demonstration of specificity required challenge with exogenous parasites. Thus, B-cell-deficient mice which had previously terminated acute *P. c. adami* infections were challenged with assorted plasmodial species. The data (Table 2) demonstrate that antibody-independent immunity resulting from *P. c. adami* infection was of limited specificity, that is, immunized mice were protected against challenge infection with either *P. c. adami* or the virulent *P. vinckei*. However, *P. berghei* and the normally avirulent 17X strain of *P. yoelii* produced fatal infections. The limited specificity of the immunity induced by *P. c. adami* is similar to that found by Cox⁸, who used immunologically intact mice in cross-protection studies. This finding remains to be explained, but it is possible that more than one immune mechanism must be activated to enable the host to resist infection with certain plasmodial species^{9–11}.

Because antibody-independent mechanisms of immunity were shown to be T-cell dependent in the model systems studied previously^{2,4}, athymic nude mice were infected with *P. c. adami* to determine if immunity to this parasite would develop in the absence of functional T cells. As shown in Fig. 1b, nude mice were unable to terminate *P. c. adami* infection and had significant parasitaemias resulting in death 7 to 9 weeks post-infection. Thus, the development of immunity to *P. c. adami* infection is dependent on the function of an intact thymus-dependent lymphocyte system.

The most interesting aspect of this study is that acute infection with *P. c. adami* was controlled by antibody-independent immune mechanisms which seem to be T-cell dependent. This finding contrasts with previous results^{2,3,5} in which survival of the host following infection with *P. yoelii* and *P. gallinaceum* was dependent on B cells (presumably antibodies). Although the nature of the antibody-independent mechanisms responsible for immunity to acute *P. c. adami* infections in B-cell-deficient mice has not been determined, it is possible that activated macrophages play a significant part. Macrophage activation has been shown to occur during murine malaria¹² and it has been suggested that factors secreted by activated macrophages may stimulate both T cells and natural killer cells to produce lymphokines and inhibitory factors, respectively¹⁰. In addition, activated macrophages may produce inhibiting factors which directly kill certain intracellular protozoa¹³. Consistent with previous observations² concerning chronic plasmodial infections in B-cell-deficient hosts was the observation that B-cell-deficient mice were unable to clear *P. c. adami* from their blood during chronic infection despite their resistance to exogenous challenge. This supports the concept of Allison and Clark⁹ that immunity to malaria is mediated by multiple mechanisms of resistance. Particular mechanisms may predominate in infections caused by certain haemoproteoan parasites and/or

Fig. 1 a, The course of *P. chabaudi* infections in eight B-cell-deficient (●) and in seven immunologically intact mice (■). 9-week old (C57BL/6 × CBA)F₁ mice were infected i.v. with 1×10^5 parasitized erythrocytes. b, The course of *P. chabaudi* infections in six athymic nude mice (●) and in five euthymic littermates (■). Mean parasitaemias are shown for 7-week old mice infected i.p. with 1×10^6 parasitized erythrocytes.

may have special significance at a particular time during the course of disease. The elucidation of these mechanisms could provide targets for development of a potential 'malaria vaccine'.

Immunotoxins: hybrid molecules of monoclonal antibodies and a toxin subunit specifically kill tumour cells

Hildur E. Blythman, Pierre Casellas, Olivier Gros, Pierre Gros, Franz K. Jansen, Francis Paolucci, Bernard Pau & Hubert Vidal

Centre de Recherches Clin Midy, Rue du Professeur Joseph Blayac, 34082 Montpellier Cedex, France

Several attempts to attack tumours in experimental systems have been made using conjugates of chemotherapeutic agents or potent toxins with antibodies (immunotoxins)¹⁻⁸. *In vitro* studies have been highly successful, showing target specificity of a high order in some cases⁶⁻⁸. However, so far, such conjugates have been inadequate *in vivo*, probably for two main reasons. First, conventional heteroclonal antibodies are perhaps inappropriate, because purification by biochemical methods leaves a large amount of non-antibody γ -globulins. The use of monoclonal antibodies may overcome this problem. Second, when whole toxins have been conjugated to antibodies there has been a strong residual nonspecific cytotoxicity due to the binding capacity of a subunit, the B-piece of the toxin. (Diphtheria toxin or ricin consist of two polypeptide subunits. The A-piece is responsible for inhibition of protein synthesis on ribosomes, and the B-piece binds to galactose residues on the cell membrane and facilitates the transmembrane passage of the A-piece.) In the present work the problem of nonspecific binding by the B-piece has been circumvented by using the A-piece only as the toxin component of immunotoxins; these immunotoxins are active both *in vitro* and *in vivo*.

A monoclonal IgM antibody directed against the Thy 1,2 differentiation antigen of mouse T cells, also present on mouse leukaemia cells (WEHI-7), was used. After precipitation of the monoclonal IgM antibody with ammonium sulphate, the antibody was purified with successive filtrations on Sepharose 6B. It was then modified with 3-(2-pyridyldithio)propionic acid in the presence of water-soluble carbodiimide and coupled to highly purified A-chain of ricin⁸. The conjugate was purified on a Sephadex G-200 column from unconjugated A-chain. The resulting immunotoxin contained on average eight A-chains per molecule, about three of which were active in an acellular protein synthesis system. The IgM component of immunotoxin retained about 70% of its activity in a complement-dependent cytotoxicity test. Inhibition of protein synthesis (PI) of viable cells *in vitro* was used to evaluate the biological activity of the conjugates⁸.

After incubation of 2×10^5 WEHI-7 cells for 16 h with different immunotoxin concentrations, a 50% inhibition of ^{14} C-leucine uptake (PI_{50}) was obtained with a 10^{-10} M concentration (Fig. 1a). Free A-chain was much less active, needing a concentration 5,000 times higher ($PI_{50} = 5 \times 10^{-7}$ M) while ricin itself was about 25 times more active than immunotoxin ($PI_{50} = 2 \times 10^{-11}$ M). A nonspecific immunotoxin directed against dextran, an unrelated antigen, behaved as free A-chain. The specificity of immunotoxin calculated as the increase of concentration needed to kill the same cells by the A-chain alone corresponded to a factor of between 2,000 and 6,000 in different batches tested (Fig. 1b). The antibody alone without complement showed no significant effect (Fig. 1c). Unconjugated antibody mixed with free A-chain behaved as free A-chain (Fig. 1c). No effect was found with an anti-Thy 1,2 immunotoxin on Thy 1,2-negative cells (Fig. 1d), although these cells had a similar sensitivity to ricin and A-chain. Complete inhibition of immunotoxin activity

Fig. 1 Specific cytotoxic activity of anti-Thy 1,2 immunotoxin. *a*, 2×10^5 WEHI-7 cells (a mouse T leukaemia expressing Thy 1,2 antigen) were incubated for 16 h with different concentrations of the test substances and then pulsed with ^{14} C-leucine for 2 h (for more details see ref. 8). ●, Ricin; ▲, A-chain; ×, anti-Thy 1,2 immunotoxin; ■, anti-dextran immunotoxin. *b*, Specificity factors demonstrate the specific cytotoxicity of immunotoxins as compared with their toxic subunit, the A-chain alone, and were drawn as arrows with the tail at the concentration (M) of free A-chain which induces 50% protein synthesis inhibition and with the head at the concentration for specific protein synthesis inhibition by immunotoxin. The specificity factors of three batches of anti-Thy 1,2 immunotoxin are compared. *c*, Thy 1,2-positive cells (WEHI-7) were used to establish specificity controls for IgM alone without complement (---●---), IgM mixed with free A-chain (---○---), A-chain (---▲---) and ricin (---●---). *d*, Thy 1,2-negative cells (BC-3A) served as controls for the specificity of the Thy 1,2 immunotoxin (---×---) as well as sensitivity to ricin (---●---) and A-chain (---▲---).

Fig. 2 Inhibition of immunotoxin activity by competition with unconjugated antibody. Increasing amounts of unconjugated antibody were added to a constant concentration of immunotoxin (5.7×10^{-9} M) which in standard tests gave 15% viability (dashed line). A threefold increase of unconjugated antibody (1.8×10^{-8} M) was needed to obtain 95% viability of target cells.

on Thy 1,2-positive cells (PI₈₅) could be obtained with a threefold molar excess of unconjugated antibody, suggesting that the binding capacity of immunotoxin is similar to that of unmodified antibodies (Fig. 2). Filter-sterilized conjugates stored in phosphate-buffered saline at -20°C for more than 6 months did not precipitate on thawing nor did they lose their immunotoxin activity.

In a first *in vivo* trial, WEHI-7 cells were injected intraperitoneally (i.p.) into BALB/c mice and each mouse was treated 1 h later with an i.p. immunotoxin injection of 30 μg conjugated A-chain, repeated 7 days later. This dose corresponded to about 1/10th of the LD₅₀ of free A-chain, which was 20 mg per kg (LD₅₀ of ricin was about 3,000 times lower, 7.5 μg per kg). With 6×10^5 cells, 9 of 10 control animals died within 39 days. Treatment with immunotoxin led to a significantly prolonged survival, as verified with the method of probits⁹. 50% survival was attained in the control group after 35 days and in the treated group after 44 days (Fig. 3b). However, with 2.4×10^5 cells no significantly prolonged survival could be obtained (Fig. 3a).

Fig. 3 *In vivo* test for immunotoxin activity. Groups of 10 BALB/c mice (Bomholtgaard) were injected i.p. with 2.4×10^5 WEHI-7 cells (a) or 6×10^5 WEHI-7 cells (b). After 1 h and 7 days, 30 μg of A-chain (bound to anti-Thy 1,2 antibody) were injected i.p. Survival was followed for 100 days.

The high specificity of immunotoxins consisting of monoclonal IgM antibodies (specificity factors of 2,000–6,000) may be attributed to the lack of non-antibody molecules or to the higher avidity of IgM over IgG antibodies. The nonspecific activity of immunotoxins on antigen-negative cells is very low and can be explained by the high purity of the A-piece replacing whole ricin. Such an effect was not convincingly demonstrated by Masuho *et al.* because their mouse cell system is insensitive to whole diphtheria toxin and cannot reveal contamination by the B-piece or whole toxin¹⁰. Specificity factors were not reported in the recent communications by Gilliland *et al.*¹¹ and Krollick *et al.*¹² because 50% nonspecific toxicity was not indicated.

Although a significant prolongation of survival time was achieved *in vivo* with our approach, the effect seemed less impressive when compared with the high potency of immunotoxin *in vitro*. This difference can perhaps be explained by the fact that the injected leukaemia cells represented less than 1% of all normal host cells expressing the Thy 1,2 antigen and thus the immunotoxin could have been absorbed by them. With repeated daily injections of immunotoxin compensating for its degradation or loss, better results might be expected. Although the immediate i.p. treatment of injected leukaemia cells with immunotoxin cannot be regarded as a model system of leukaemia treatment, it represents a highly sensitive test system. Whereas, *in vitro*, 50% survival of tumour cells is measured, *in vivo*, even single cell clones escaping the treatment will induce tumours some time later.

Immunotoxins retained most of their complement fixing activity but, as human complement is thought to be relatively inefficient *in vivo* for the destruction of tumour cells, the complement-independent activity of immunotoxins may represent a promising means of passive immunotherapy of cancer.

This work was supported in part by a grant from the Délégation Générale à la Recherche Scientifique et Technique, Paris, France. WEHI-7 and BC-3A cells were obtained from the Cell Distribution Center, the Salk Institute.

Further molecular complexities of H-2 K- and D-region antigens

P. Démant & Dagmar Iványi

Division of Genetics, Antoni van Leeuwenhoek Huis, The Netherlands Cancer Institute, Amsterdam, The Netherlands

The K and D regions of the H-2 gene complex are highly polymorphic^{1,2} and control cell-surface structures involved in the H-2 restriction of cytotoxic T lymphocytes^{3,4}. Originally it was assumed that each of these regions controlled only one type of antigenic molecule, H-2K and H-2D, respectively^{2,5–7}. The finding that the D region controls H-2L^{8–10} and H-2M¹¹, as well as H-2D, molecules suggests that the system of H-2 antigens is more complicated. We demonstrate here previously unknown

H-2 molecules detected by anti-K- and D-region alloantisera in co-capping experiments. Three different types of molecule, distinct from Ia and Qa antigens, are distinguished in the products of the D^{dx} region, and two in the products of the D^k and K^d regions. Analysis of the antigenic heterogeneity of K- and D-region products may further understanding of the function of these regions in cell-mediated immunity.

Antibodies against the products of the K and D regions detect molecules of molecular weight 45,000 associated with a β_2 -microglobulin in chain¹²⁻¹⁴. This was demonstrated also for the H-2L¹⁵⁻¹⁷ and H-2M¹⁸ molecules. Alloantibodies against these antigens detect either specificities characteristic for a single allele, for example K^b or D^d (private specificities), or the common or cross-reactive specificities (public specificities) shared by products of several different alleles^{1,2,5,6,19}. Antisera against the public or private specificities were used to cap the respective K- and D-region products on T lymphocytes of C3H.LG and GRS ($H-2^{dx}$) and C3H.OH ($H-2^{oz}$) strains. After the capping procedure, the cells were tested with the antiserum used for capping as well as with other anti-private and anti-public antisera to see whether any molecules reactive with these antisera remained non-redistributed. Two techniques, indirect immunofluorescence and resistance to complement lysis (lyso-strip), were used as described earlier¹¹. The two assays never gave discordant results¹¹.

In earlier observations^{7,8,20}, capping with antisera against the public specificities removed all molecules reactive with antisera against the pertinent private specificity. We show that selected anti-public sera, however, fail to do so. Such sera were used to differentiate further the K- and D-region products. Table 1 summarizes the analysis of the H-2 molecules controlled by the $H-2^{dx}$ haplotype (K^d, I^f, S^f, D^{dx}) which was previously shown to control three molecules: H-2K^d, H-2D^{dx} and H-2L^{dx} (ref. 21). Data in Table 1 show that, using suitable antisera, five different H-2 molecules can be distinguished in this haplotype. Antiserum ASA-26B was made against the products of the D^{dx} region (the $H-2^{dx}$ and recipient have the same K^d region) and it contains two kinds of antibodies—one reactive with the H-2D^{dx} molecule and another with the H-2L^{dx} molecule²¹. The latter antibodies reacted with a public specificity common to H-2L^{dx} and some H-2.1-positive molecules produced by other haplotypes. Therefore, they could be removed from the ASA-26B by

absorption with C3H ($H-2^k$) cells leaving only anti-H-2D^{dx} antibodies. In capping experiments, the serum ASA-26B absorbed with (abs.) C3H (anti-H-2D^{dx}) did not cap all molecules detected by the antiserum ASA-26B (thus defining the H-2L^{dx} molecule, ref. 21 and Table 1). Antiserum ASA-26B abs. C3H did cap all molecules reactive with two other anti-public antisera, ASA-30C and ASA-14F, indicating that these sera contained no antibodies reactive with either H-2L^{dx} or K-region molecules. One of these sera, ASA-30C, however, failed to cap all molecules reactive with the ASA-26B abs. C3H and ASA-14F indicating that besides the H-2L^{dx} molecules (which are not capped by ASA-26B abs. C3H and ASA-14F) two other D^{dx} -region molecules can be distinguished: both can be capped by the ASA-26B abs. C3H and ASA-14F, but only one of them is capped by the ASA-30C. Similarly, the antisera D-31 and S3E which react with the K-region products of the $H-2^{dx}$ haplotype in capping experiments define two serologically different molecules. This is seen by the failure of the serum S3E to cap all molecules reactive with the serum D-31. Thus, two molecules can be distinguished in the K^d region: one which can be capped by the serum D-31 and S3E, and another which can be capped by D-31 but not by S3E. The anti-Ia antibodies are not responsible for the complexities of the K region described here as our assay does not detect Ia antigens on T lymphocytes^{8,11}. Moreover, these results were obtained with the K^d -region products in the cells carrying the $H-2^{dx}$ haplotype (K^d, I^f, S^f, D^{dx}) even after removal of anti-Ia antibodies by absorption (Table 1,*). The antiserum S3E cannot contain any anti-Ia antibodies, because both the donor and recipient are I^k .

Note that, although the genetic mapping of these molecules is only inferential as $H-2^{dx}$ is a natural recombinant, there is no doubt about the serological distinctness of these molecules and their H-2-like characteristics (ASA-26 and ASA-30 do not contain anti-Ia antibodies and in the strain GRS they do not react with Qa antigens²¹, and, as discussed above, the two K^d -region molecules are not Ia antigens).

A similar complexity was detected in the products of the $H-2^{oz}$ haplotype (K^d, I^d, S^d, D^k) (Table 2). The D^k -region products which are capped by anti- D^k -private serum ASA-11 or D-32 cannot be completely capped by the antiserum ASA-14. Similarly, the products of the K^d region which can be capped by the anti- K^d -private serum D-31 cannot be completely capped by

Table 1 Molecular relationships between H-2 specificities analysed by antibody-induced redistribution (capping) and resistance to lysis (lyso-strip) on T lymphocytes of the C3H.LG and GRS/Mtv-2- strains (both $H-2^{dx}$, K^d, I^f, S^f, D^{dx})

Strain C3H.LG was supplied by Dr M. Cherry. It carries the $H-2^{dx}$ haplotype which is indistinguishable serologically from that of GRS/A (P.D. and M. Cherry, unpublished data). The strain GRS/Mtv-2- was prepared from the GRS/A strain as described²⁸. It has the same H-2 haplotype as GRS/A and C3H.LG (data not shown). Results with the two strains were identical in cytotoxicity. Immunofluorescence was done predominantly on GRS/Mtv-2- cells. For the first antiserum, T lymphocytes were incubated with anti-H-2 serum + fluorescein isothiocyanate-labelled anti-IgG in capping conditions¹¹. The second antiserum was incubated in non-capping conditions¹¹ with addition of rhodamine-labelled anti-IgG or with complement. Antisera: ASA-26B (B10.D2 × A.CA)F₁ anti-GRS ($d \times f$) anti- dx (this antiserum ASA-26B contains anti-H-2.63, anti-H-2.1-like and non-H-2 antibodies²¹). These non-H-2 antibodies do not react with antigens of the C3H strain and its congenic lines (data not shown). Absorption with C3H or B10.A cells removes anti-H-2.1-like but not anti-H-2.63 activity²¹; ASA-30C (C3H × BALB/c- $H-2^{dm2}$)F₁ anti-BALB/cHe; ASA-14F ((A.SW × BALB/c)F₁ anti-A/Sn); D-31 (B10 × A)F₁ anti-B10.D2; and S3E (B10.RIII × C3H)F₁ anti-B10.AKM. Antiserum D-31 was supplied by the NIH serum bank. In some experiments NIH antiserum Ia.11,16 was used in place of D-31. This serum was prepared in the same strain combination and gave identical results. IF, immunofluorescence: % of cells with red label outside the green caps observed in capping experiments. C, cytotoxicity: redistribution results expressed as % of cells killed by the second antiserum and complement after incubation with the first antiserum + anti-IgG. Several serial dilutions were tested. ND, not determined.

* The same results were obtained with antiserum D-31 absorbed with B10.P cells (which absorb all activity with the strain B10.M, $H-2^f$, but not with C3H.OH, C3H.LG or GRS cells).

For first and second antisera, see Table 1 legend. Antisera: ASA-11 (B10.AKM × C3H.B10)F₁ anti-C3H; D-32 (B10.A(2R) × C3H.SW)F₁ anti-C3H; ASA-14 (A.SW × BALB/c)F₁ anti-A/Sn; D-31 (B10 × A)F₁ anti-B10.D2; S3E (B10.RIII × C3H)F₁ anti-B10.AKM. The antisera D-31 and D-32 were supplied by the NIH serum bank. IF, immunofluorescence, and C, cytotoxicity; see Table 1 legend. ND, not determined.

* Several anti-public sera caused complete capping or patching of antigens detected by anti-private sera, for example ASA-1H capped for D-31b and D-5AF for ASA-11 (ref. 29).

† This reaction is not due to anti-Qa antibodies. ASA-11 was made by immunization against C3H/HeA cells. No Qa antigens were described in C3H strains. Moreover, we tested the tissue distribution of the antigens detected by this serum and found that liver and kidney tissue can absorb all activity of this serum with peripheral lymph node cells. Thus, the tissue distribution of H-2D1^k and H-2D2^k is like that of H-2 and not Qa.

the antiserum S3E. Thus, at least two different molecules can be distinguished among the D^k -region products. One can be capped by both ASA-14 and ASA-11 or D-32, the other only by the anti-H-2.32 sera (ASA-11, D-32) but not by ASA-14. Two distinct K^d products can be distinguished—one which can be capped by the anti-H-2.31 serum D31 as well as by the antiserum S3E, and another which can be capped only by the anti-H-2.31 serum and not by the antiserum S3E. No known Qa or TL antigens are involved in the complexities of the $D^k D^d$ -region antigens described here (see above and Table 2,†). The failure of some anti-public sera to cap all molecules reactive with the anti-private sera is not due to some intrinsic nonspecific properties of such anti-public sera. For example, the serum ASA-14 caps only one of the two D^k molecules (Table 2) but it can cap two different D^d products (Table 1).

Our data suggest, but do not prove, that the two D^k molecules described here may share the same private specificity, H-2.32. Alternatively, they could each carry a different unique specificity, but be indistinguishable because of the lack of suitable recombinants or mutants. The possibility that the antiserum ASA-14 does not react with an H-2.32 (ASA-11)-positive molecule, but with a molecule which co-caps with the H-2.32-positive molecules (as was suggested for some antigens on virally infected cells²²), also cannot be ruled out. The same interpretations can also be applied to the serological characteristics of the two different K^d -region molecules and the two types of D^d molecule capped by the ASA-26B abs.C3H. These uncertainties have to be resolved by immunoprecipitation studies. The relationship of the two D^k -region molecules to the H-2L molecules is unclear. Using different anti-H-2.32 and anti-H-2.1 sera we failed to confirm the original report²³ on the H-2.1-positive molecules detected after capping of H-2.32 molecules. Either the H-2.32-negative D^k -region products do not exist, or they carry their own 'unique' specificity and the antibodies against it contaminate the anti-H-2.32 sera.

Previously we demonstrated three different molecules in the D -region products of H-2^d (ref. 11). These are H-2L^d which cannot be capped by antisera against the specificity H-2.4, and H-2D^d and H-2M^d which can be capped by anti-H-2.4 sera, but the latter not by some anti-H-2.28 sera (S1E, (B10.RIII × C3H)F₁ anti-B10.A(2R)). Thus, together with the two K^d -region molecules, the H-2^d haplotype controls at least five serologically distinct H-2-like molecules.

It is not known whether the heterogeneity of the K - and D -region antigens described here reflects genetic complexity of these regions or is produced epigenetically. The former

explanation is supported by our observation that the mutant H-2^{dm1} does not express any detectable H-2M^d molecules¹¹, although even here post-translational mechanisms are not ruled out. Where several different H-2 molecules map into the same genetic region, the question of the respective genes becomes unclear. Until informative recombinants are found, these molecules would seem to be the products of pseudoallelic genes and the H-2 terminology which indicates, for example, that H-2D^d is 'allelic' or 'homologous' to H-2D^a, or H-2L^d is allelic or homologous to H-2L^{dx}, is based on apparent general serological similarities of the respective molecules, and may not be correct. Until suitable recombinants are found or other reliable genetic, biochemical or functional criteria of 'allelism' become available, it is very difficult to be certain about the relationships of molecules detected in the products of different regions. Therefore, we have used here a neutral terminology for the 'new' molecules, which makes no unwarranted assumptions about genetics and can be replaced by a more specific one when more information becomes available. Thus, the two molecules in the D^k region are named H-2D1^k and H-2D2^k, the two new D^d molecules are named H-2D1^{dx} and H-2D2^{dx}, and the two K^d -region molecules H-2K1^d and H-2K2^d.

It is also not certain whether each non-mutant haplotype produces all the known types of H-2 molecules. Furthermore, an H-2 molecule might be controlled by more than one gene⁹. A similar possibility was indicated for HLA (histocompatibility) antigens by serological²⁴ and biochemical²⁵ studies. If this is the case, the notion of allelic genes in its simplest form is not applicable for the genes controlling the K - and D -region products.

Considerable physicochemical heterogeneity of K - and D -region products had been previously detected by two-dimensional electrophoresis^{26,27}. These data were, however, never connected with the antigenic diversity of H-2 molecules. The analysis of the antigenic heterogeneity of K - and D -region products may contribute to the understanding of the structure of these regions and of their function in cell-mediated immunity.

We thank Ms M. A. J. M. Treur-Mulder and A. E. Bezemer for technical assistance and Ms C. E. van Vemde for preparation of the manuscript.

³H-baclofen and ³H-GABA bind to bicuculline-insensitive GABA_B sites in rat brain

D. R. Hill & N. G. Bowery

Department of Pharmacology, St Thomas's Hospital Medical School, London SE1 7EH, UK

The presence of a novel receptor for the neurotransmitter γ -aminobutyric acid (GABA) on peripheral autonomic nerve terminals and in mammalian brain slices has been described recently^{1–4}. This receptor differs from the classical GABA site as it is unaffected by recognized GABA antagonists such as bicuculline and is not sensitive to the majority of accepted GABA-mimetics such as 3-aminopropanesulphonic acid (3-APS) or isoguvacine. We propose to designate the classical site as the GABA_A and the novel site as the GABA_B receptor. The β -*p*-chlorophenyl derivative of GABA, baclofen, is stereospecifically active at the GABA_B site whereas it is devoid of activity at the classical GABA_A site^{2,5–9}. We now report that high-affinity saturable binding of ³H-baclofen and ³H-GABA to the GABA_B site can be detected in fragments of crude synaptic membranes prepared from rat brain. The results support the concept of a novel GABA receptor within the mammalian brain and show that GABA and baclofen can compete for the same recognition site.

The procedure adopted for this study was essentially that used by others for the detection of GABA_A sites with one notable difference—the inclusion of divalent cations in the incubation medium. Our studies have indicated that saturable high-affinity binding of ³H-baclofen is detectable in the presence of either Ca²⁺ or Mg²⁺ ions. Crude synaptic membranes were prepared by the method described by Zukin *et al.*¹⁰ and although saturable binding of ³H-baclofen (β -(4-chloro-3-³H(*N*))phenyl- γ -aminobutyric acid, 8.8 Ci mmol⁻¹) could be detected in freshly prepared and washed membranes, frozen and thawed material was routinely used. Pellets were allowed to thaw for 15 min at room temperature before suspension in Krebs–Henseleit solution (KHS), or where indicated, Tris-HCl buffer (50 mM, pH 7.4) plus CaCl₂ (2.5 mM). The tissue was maintained at 20 °C for 45 min before washing four times in fresh medium. Assays were terminated by centrifugation at 7,000g for 10 min. The specific saturable portion of binding was that displaced by an excess (100 μ M) of ($\pm$)baclofen, (–)baclofen or GABA.

In the presence of Tris-HCl buffer alone, only $5.5 \pm 0.64\%$ (mean $\pm$ s.e.m., $n = 4$ in triplicate, $P < 0.01$ paired comparison *t*-test) of the total ³H-baclofen bound could be displaced by

unlabelled ligand. In Tris-citrate buffer (50 mM, pH 7.4) no displacement could be detected (5–30 min incubation at room temperature; 5–20 nM ³H baclofen). By contrast, when KHS was used instead of Tris buffer, $21 \pm 1.1\%$ (20 nM ³H-baclofen, $n = 28$ in triplicate, equivalent to $3,712 \pm 234$ d.p.m. per mg protein) of the total could be displaced by excess unlabelled GABA, ($\pm$)baclofen or (–)baclofen (100 μ M in each case). The maximal displacement produced by each of these was the same and the extent of displacement was dose dependent.

To determine which of the ionic constituents of KHS was responsible for the emergence of the saturable component the assay was performed in Tris-HCl buffer to which one of the individual components was added. Each salt was added at the concentration present in KHS. The addition of either CaCl₂ (2.5 mM) or MgSO₄ (1.2 mM) to Tris-HCl buffer resulted in the appearance of saturable binding comparable with that observed in KHS. The addition of KCl (5 mM) or NaCl (143 mM) failed to increase the small degree of saturable binding observed in Tris-HCl alone. Thus K⁺, Na⁺ and Cl[–] ions do not seem to be

Fig. 1 Analysis of the binding of ($\pm$)³H-baclofen to rat brain synaptosomal membranes. Crude synaptic membranes were prepared by homogenization of whole rat brain in 10 vol ice-cold 0.32 M sucrose. The homogenate was centrifuged at 1,000g for 10 min and the supernatant collected and recentrifuged at 20,000g for 20 min. The pellet obtained from this second centrifugation was dispersed in distilled water (volume equal to original sucrose solution) and centrifuged at 8,000g for 20 min. The supernatant together with the buffy layer on the pellet was then centrifuged at 50,000g for 20 min. The resulting pellet was resuspended in distilled water and again centrifuged at 50,000g for 20 min. The final pellet was stored at –15 °C. For the assay in *a*, pellets which had been frozen for at least 16 h were allowed to thaw for 20 min at room temperature before resuspension in KHS. The pellet obtained from the equivalent of one rat brain was resuspended in 10 ml KHS. The suspension was incubated for 45 min at 20 °C before centrifugation at 7,000g for 10 min. This washing procedure was repeated three more times allowing 15 min incubation with each addition of KHS. The final pellet was resuspended in KHS (~1 mg protein per 0.8 ml KHS) for the assay. Protein concentrations were determined by the method of Lowry *et al.*²⁰. To each 0.8-ml aliquot of membrane suspension 0.1 ml KHS containing various concentrations of unlabelled ($\pm$)baclofen and 0.1 ml KHS containing a fixed concentration of ($\pm$)³H baclofen was added. The range of final concentrations of unlabelled baclofen was 10 nM–100 μ M. The final ³H-baclofen concentration was 20 nM. The mixture was incubated for 10 min at 20 °C and then centrifuged at 7,000g for 10 min. The supernatant was aspirated off and the pellet blotted dry before the addition of 100 μ l Soluene. The tritium level of each pellet was determined by liquid scintillation spectrometry. As the total amount bound was <3% of the radiolabel in the incubation medium, the 'free' concentration was taken as equivalent to the total tritium concentration. The same procedure was adopted in *b* as in *a*, except that Tris-HCl solution containing 2.5 mM CaCl₂ (instead of KHS) was used throughout the assay. In *a*, data derive from four separate experiments performed in triplicate at each concentration, and in *b* from a single experiment of triplicate determinations at each concentration. This experiment was repeated twice more yielding the same results.

Table 1 Comparative inhibitory activities of GABA analogues on specific ^3H -baclofen binding to synaptosomal membranes, evoked ^3H -noradrenaline release from rat isolated atria and twitch responses of mouse isolated vas deferens

essential for saturable ^3H -baclofen binding. The dependence on divalent cations could explain the difference in displaceable binding detected in Ca^{2+} -free Tris-HCl buffer compared with Tris-citrate buffer. In Tris-HCl buffer any Ca^{2+} remaining in the tissue could promote binding, whereas in Tris-citrate buffer the Ca^{2+} would be chelated and therefore unavailable for binding.

Experiments performed with varying concentrations (0–10 mM) of CaCl_2 indicated that 2.5 mM was optimal. At concentrations <1 mM the proportion of specific binding was decreased (for example, at 0.6 mM the specific portion was 30% less than at 2.5 mM). At concentrations >2.5 mM (5 and 10 mM) binding was, if anything, reduced.

Subsequent experiments to determine the characteristics of ^3H -baclofen binding were performed in KHS which contains 2.5 mM CaCl_2 and 1.2 mM MgSO_4 . This seemed appropriate as our earlier studies^{1–3} on the GABA_B site had used this solution, and as binding was apparently not Na^+ dependent, it was unlikely to be due to transport of the ligand but rather to binding at a receptor site. Moreover, the time course and lack of temperature dependence of ^3H -baclofen binding would support this. Transport of the ligand would be expected to increase with temperature but this was not observed. The amount of ^3H -baclofen specifically bound to membranes incubated at 20 °C for up to 60 min was constant. A minimum contact time with the ligand was achieved by centrifuging the incubation mixture for 5 (instead of 10) min immediately after adding the tritium. The total time taken until removal of the supernatant after centrifugation was 8 min. Even at this time saturable binding was not significantly different from that obtained after longer periods of incubation. Ten-minute incubation periods were routinely used in further experiments but clearly this was not critical.

Analysis of the binding of ^3H -baclofen in the presence of KHS revealed two saturable components. These are shown graphically in Fig. 1a using the Scatchard transformation. The kinetic parameters ($K_{d1} = 81.7 \pm 40$ nM, $B_{\text{max}1} = 0.68 \pm 0.22$ pmol per mg protein; $K_{d2} = 5.3 \pm 1.59$ μM , $B_{\text{max}2} = 6.89 \pm 0.8$ pmol per mg protein) were determined by nonlinear least-squares optimiza-

tion using a digital computer¹¹. The data were weighted according to the method of Ottaway¹². Analysis of data obtained in identical experiments but using Tris-HCl plus CaCl_2 (2.5 mM) instead of KHS revealed only a single saturable component (Fig. 1b). The parameters for this component ($K_d = 132$ nM, $B_{\text{max}} = 1.1$ pmol per mg protein, Hill coefficient = 0.997) were comparable with the high-affinity component observed in KHS. The Hill coefficient of 0.997 suggests that in Tris-HCl plus CaCl_2 binding occurs at an homogeneous site in accordance with the law of mass action.

Several unlabelled analogues have been examined for their ability to displace ^3H -baclofen from its binding sites. GABA and (–)baclofen, which were equally effective, are the most potent so far examined. (+)Baclofen was much less active (<0.001). The dose-dependency of these displacing agents is shown in Fig. 2 together with data obtained for 3-APS, muscimol, isoguvacine and bicuculline methobromide. Clearly 3-APS was only very weakly active (<0.003) and isoguvacine and bicuculline methobromide were devoid of activity. A summary of the relative potencies of the analogues is given in Table 1. There is a marked similarity between these data and those obtained previously in rat atrium and vas deferens where GABA and baclofen reduce the evoked output of transmitter. The implication is therefore that a common site exists within these systems.

Many workers have shown that baclofen is at best only weakly active in displacing ^3H -GABA from synaptic membranes suspended in Tris-citrate buffer^{13–16}. The average IC₅₀ for baclofen from these studies is >100 μM and no stereospecificity has been observed. We concur with this. However, on adding CaCl_2 (2.5 mM) to Tris-HCl buffer an additional component of ^3H -GABA binding emerges. Frozen and washed membranes were suspended in Tris-HCl buffer (50 mM, pH 7.4) containing 2.5 mM CaCl_2 and the binding assayed performed as described in Fig. 1 legend but instead of using ^3H -baclofen, ^3H -GABA (4-amino- π [2,3- ^3H]butyric acid, 10 nM, 57 Ci mmol^{–1}, Amersham) was used. Isoguvacine (final concentration 40 μM) was

present in all the assay tubes to saturate GABA_A sites. This concentration of isoguvacine produced maximal inhibition of GABA_A binding whereas it inhibited GABA_B binding by less than 10% (Fig. 2). The specific portion of GABA displaced by

Fig. 2 Inhibition of $(\pm)^3\text{H}$ -baclofen binding by GABA-related compounds. Assays were performed according to the method described in Fig. 1 legend. Unlabelled analogues at final concentrations between 0.01 and 100 μM were added to each incubation mixture together with ^3H -baclofen (20 nM final concentration). The incubation was terminated by centrifugation at 7,000g for 10 min. Specific binding was taken as the amount of label displaced by $(\pm)$ -baclofen (100 μM). The amount displaced by individual concentrations of each analogue (log molar, abscissa) is expressed as a percentage of the total displaced by 100 μM $(\pm)$ -baclofen within the same experiment. The data have been separated for clarity. *a* Shows the effect of GABA (●), muscimol (Δ), isoguvacine (▼) and bicuculline methobromide (□). *b* Shows the effects of $(-)$ -baclofen (○), $(\pm)$ -baclofen (■), 3-aminopropanesulphonic acid (×) and $(+)$ -baclofen (▲). Each point is the mean of three experiments performed in triplicate. Standard error values were in all cases $<8\%$, and have been omitted for clarity. More than 95% of the tritium bound to the synaptosomal pellets corresponded to authentic ^3H -baclofen as determined by TLC in two systems. Six pellets (after incubation for 30 min in ^3H -baclofen) were resuspended in 1 ml 10% trichloroacetic acid and allowed to stand at room temperature for 1 h before centrifugation at 8,500g for 5 min. This procedure extracted $>86\%$ of the radioactivity of the supernatant. Aliquots (100 μl) of the supernatant were then streaked onto two silica gel plates together with markers comprising 1 pmol ^3H -baclofen, 20 μg $(\pm)$ -baclofen and 20 μg GABA. All marker solutions were prepared in 10% trichloroacetic acid. The plates were run in butanol/acetic acid/water (120:30:50) or ethanol/ammonia(0.880)/water (180:10:10). Unlabelled baclofen and GABA were visualized with 0.2% 1,2-naphthoquinone-4-sulphonic acid in 5% sodium carbonate solution and the position of labelled materials was determined by scraping sequential portions of the gel into 1 ml water before the addition of scintillation fluid. The major (*in vivo*) metabolite of baclofen, γ -hydroxy- β -chlorophenyl butyric acid was co-chromatographed on separate plates impregnated with a fluorescent indicator (Merck Keisegel 60 F₂₅₄). GABA and baclofen were also applied to these plates as markers. The metabolite and baclofen were visualized by UV illumination and GABA and baclofen again by staining. None of the pellet radioactivity corresponded to this metabolite. The experiment was repeated twice more and yielded the same results.

Fig. 3 Illustration of baclofen-sensitive GABA binding sites on rat brain synaptic membranes using ^3H -GABA. Membranes were prepared as described in Fig. 1 legend. Thawed pellets were similarly washed four times but instead of Krebs-Henseleit solution, Tris-HCl buffer (50 mM, pH 7.4) containing 2.5 mM CaCl₂ was used. The binding assay was also performed in a similar manner to the ^3H -baclofen assay except ^3H -GABA (10 nM) was used as the ligand. Tris-HCl plus Ca²⁺ solution was used as the incubation solution to prevent any Na⁺-dependent binding. Isoguvacine HCl (40 μM) was also present in the final incubation mixture in all samples to suppress Ca²⁺-independent GABA binding to GABA_A sites. At this concentration, isoguvacine is without effect on ^3H -baclofen binding (Fig. 2) whilst maximally displacing ^3H -GABA binding at GABA_A sites. Specific binding of ^3H -GABA was that fraction ($38 \pm 2\%$) displaced by unlabelled $(-)$ -baclofen (100 μM). Displacement by other analogues is expressed as a percentage of that produced by $(-)$ -baclofen (100 μM) in the same experiment. Each point is the mean of three determinations performed in triplicate. Standard errors were $<5\%$. ●, GABA; ○, $(-)$ -baclofen; Δ, muscimol; ▲, $(+)$ -baclofen.

100 μM $(-)$ -baclofen represented $18,751 \pm 1,511$ d.p.m. per mg protein which was equivalent to $38 \pm 2\%$ of binding ($n = 13$ in triplicate). This Ca²⁺-dependent GABA binding was saturable and Scatchard analysis indicated a single component ($K_d = 77$ nM, $B_{\text{max}} = 1.22$ pmol per mg protein, Hill coefficient = 1.06 mean of six experiments). The structural specificity of compounds which inhibited binding was comparable with that observed for displacement of ^3H -baclofen (Fig. 3). The 'cross-displacement' between GABA and baclofen strongly suggests that they have affinity for a common recognition site which differs from the 'classical' GABA_A site.

We believe that this is the first binding system to be described which is dependent on the presence of divalent cations. Enhancement of the binding of opiate agonists and glutamic acid by divalent cations has been demonstrated. However, the activation of ^3H -glutamate binding by calcium is markedly temperature dependent and persists after removal of the cation^{17,18}. This does not occur at the GABA_B site. The activation of Na⁺-independent ^3H -dihydromorphine binding by calcium is very weak and it is unlikely that calcium regulates opiate receptor binding¹⁹. By contrast, calcium or magnesium seem to be necessary to detect binding at the GABA_B site.

Thus, we have shown that tritiated baclofen and GABA can bind in a saturable manner to a receptor site on mammalian synaptic membranes, and that GABA and $(-)$ -baclofen have equal affinity for this binding site. Pharmacologically the site seems to be identical to that previously described on peripheral nerve terminals¹⁻³ (Table 1) and in mammalian brain slices⁴. Bicuculline-insensitive GABA sites seem to be present on nerve terminals and, when activated, reduce evoked neurotransmitter release. Therefore, the GABA_B binding site described in this study is probably present on nerve terminals.

We thank Ciba-Geigy Basle for supplies of ^3H -baclofen and the enantiomers of baclofen, and Ciba-Geigy Horsham for financial assistance. Isoguvacine, bicuculline methobromide and

THIP were given by Drs J. F. Collins and P. Krogsgaard-Larsen. We also acknowledge the assistance of Dr R. White, who performed the computer analysis, and Mrs J. Andrews, who typed the manuscript. D.R.H. is an SRC Scholar.

An oestrogen receptor activator protein in rat uterine cytosol

T. N. R. V. Thampan & James H. Clark

Department of Cell Biology, Baylor College of Medicine, Houston, Texas 77030, USA

Earlier reports of oestrogen receptor binding to DNA¹⁻⁴ indicated that a protein which does not bind oestrogen might be involved in the conversion of the 4S oestradiol receptor to the 5S form but no direct evidence for the existence of this protein was presented. This receptor transformation or activation step is thought to be a requirement for events in the nucleus. We considered it likely that such a protein might be similar to the cytoplasmic proteins which stimulate eukaryotic RNA polymerases⁵⁻¹¹. These are basic proteins which are not adsorbed to DEAE cellulose and have a sedimentation coefficient of ~3S. To examine this possibility, we fractionated unlabelled uterine cytosol by DEAE-cellulose chromatography. Unlabelled cytosol was used to avoid the possibility that such a factor might be retained on the column as a component of the receptor-oestradiol complex. Here we present evidence of a protein present in uterine cytosol which forms a complex with the 4S form of the oestrogen receptor to produce a 5S-activated form. This activated form binds to uterine nuclei, DNA-cellulose and native calf thymus DNA. The cytosol protein, which we call receptor activation factor, does not bind oestradiol, has a sedimentation coefficient of ~3S and does not bind to DEAE-cellulose.

Adult female rats of the Holtzman strain were used 2 weeks after ovariectomy. All experimental procedures were carried out at 4 °C. Two uteri were homogenized in 10 ml TETK buffer (0.01 M Tris-HCl, 0.001 M EDTA, 12 mM thioglycerol and 0.075 M KCl, pH 7.8) and centrifuged at 10,000 r.p.m. for 15 min. The supernatant was centrifuged at 45,000 r.p.m. for 2 h and the cytosol fraction recovered. DEAE-cellulose (Whatman DE 52) was equilibrated with TETK buffer and washed extensively with the buffer before chromatography.

Fig. 1 Oestradiol binding to uterine cytosol fractions as a function of hormone concentration. Fraction I (○) and fraction II (●) of uterine cytosol were prepared as described in the text. Aliquots of each fraction were incubated with varying concentrations of ³H-oestradiol (specific activity 90 Ci mmol⁻¹) in the presence or absence of 100-fold excess of DES in a total volume of 350 μl at 30 °C for 30 min. After incubation, the samples were cooled in ice and 500 μl of a 60% suspension of HAP added. The samples were vortexed, left in ice for 10 min and centrifuged at 3,000 r.p.m. for 5 min. The HAP pellet was washed three times with 0.01 M Tris-HCl, 0.001 M EDTA, pH 7.4. The pellet was then extracted with 1 ml ethanol and the radioactivity assayed using ACS (Amersham). Protein was estimated according to Lowry *et al.*¹⁵.

Fig. 2 Effect of fraction I on the sedimentation behaviour of the fraction II-oestradiol complex. Fraction II (45 μg of protein which contained the cytosol oestrogen receptor) was incubated with 10 nM ³H-oestradiol in the presence or absence of fraction I (40 μg protein) at 30 °C for 30 min. The labelled materials were subjected to density-gradient centrifugation on 5-20% linear sucrose gradients (in TETK buffer containing 0.3 M KCl) at 45,000 r.p.m. for 16 h. Parallel gradients containing 1 μM DES in addition to ³H-oestradiol were run to compute the specific hormone binding. Human γ globulin and ovalbumin were used as sedimentation markers. ●, Fraction II + TETK buffer; ○, fraction I + fraction II.

Cytosol was applied to the DEAE-cellulose column (2 × 6 cm) and allowed to enter the gel, which was washed with TETK buffer after 1 h. The fractions that did not adsorb to the DEAE-cellulose were recovered (fraction I). The column was then washed with TETK buffer containing 0.3 M KCl and the eluted material collected (fraction II). Solid (NH₄)₂SO₄ was added to the two fractions to 75% saturation to precipitate the

macromolecules and the precipitate was dissolved in the required volume of TETK buffer (2 and 4 ml for fractions I and II respectively).

Concentration-dependent binding of ^3H -oestradiol to the macromolecules in fractions I and II was studied using the hydroxyapatite (HAP) assay method as described in Fig. 1 legend and in Clark and Peck¹². Fraction II showed a saturation curve typical of hormone-receptor preparations, but no significant binding of oestradiol was found in fraction I (Fig. 1). The effects of the addition of fraction I on hormone-binding properties of fraction II were examined. Fraction II-oestradiol complex sedimented as a 4S (3.8S) peak on sucrose density gradients in the absence of fraction I. However, when equivalent protein concentrations of fraction I were mixed with fraction II two peaks of bound hormone were observed, one sedimenting at

Fig. 3 *a*, Effect of addition of fraction I on the binding of fraction II-oestradiol complex to isolated uterine nuclei. Nuclei (25 μg DNA) were incubated with 10 nM ^3H -oestradiol $\pm$ 1 μM DES and fraction II (40 μg protein) either in the presence (●) or absence (○) of fraction I (20 μg protein) at 30 °C for various time periods. At the end of the incubation the tubes were centrifuged and the pelleted nuclei washed three times with TETK buffer. The ^3H -oestradiol bound to the nuclei was extracted with ethanol and the bound hormone calculated. DNA was measured according to the procedure of Burton¹⁶. *b*, Binding of fraction II-oestradiol complex to DNA-cellulose as a function of the concentration of fraction I proteins. DNA-cellulose (10 μg DNA) was incubated at 30 °C for 30 min with 10 nM ^3H -oestradiol, fraction II (50 μg protein) and various concentrations of fraction I (●). Similar experiments were done with various levels of fraction II in the absence of fraction I (○). Parallel incubations with 1 μM DES were also done to establish specific binding. After incubation, the samples were cooled in ice and 1 ml of cold TETK buffer added. The DNA-cellulose was pelleted after centrifugation for 5 min at 4 °C (3,000 r.p.m.) and washed three times using 1 ml volumes of TETK buffer. The radioactivity bound to DNA-cellulose was extracted with ethanol. The counts associated with the DNA-cellulose in the presence of 1 μM DES were subtracted from the total counts to assess the specific binding of the receptor to DNA-cellulose.

Fig. 4 Effect of fraction I on the binding of fraction II to native calf thymus DNA. 20 μg DNA was incubated with fraction II (40 μg protein) and 10 nM ^3H -oestradiol in the presence (●) or absence (○) of fraction I (30 μg protein) at 30 °C for 30 min. Centrifugation on linear 5–20% sucrose gradients (in TETK buffer) was done at 45,000 r.p.m. for 2 h. The dotted line represents absorbance at 260 nm.

5S (4.8S) and the other at 4S (3.8S) (Fig. 2). In the presence of fraction I, radioactivity associated with the 4S fraction was reduced to less than 50% of that detected in its absence. The radioactivity that was lost from the 4S appeared in the 5S peak. In all these cases the protein fractions were incubated with 10 nM ^3H -oestradiol in the presence or absence of 1 μM diethylstilboestrol (DES) at 30 °C for 30 min before density-gradient centrifugation and the nonspecific binding was subtracted from the total to determine specific binding.

Time-dependent binding of fraction II-oestradiol complex to isolated uterine nuclei was investigated. Uterine nuclei were purified as follows: uteri were homogenized in TMKC-sucrose buffer (10 mM Tris-HCl, pH 7.5, 5 mM MgCl_2 , 25 mM KCl, 1 mM CaCl_2 and 0.5 M sucrose) using a ground glass homogenizer and centrifuged at 2,000 r.p.m. (Beckman JS7.5 rotor) for 10 min. The pellet was gently homogenized in the same buffer containing 0.25% Triton X-100 and 0.25% NP40, filtered through two layers of organza and centrifuged. The pellet was resuspended in the buffer, filtered through organza and centrifuged twice to remove the detergent. The washed pellet was resuspended in TMKC buffer containing 1.9 M sucrose and centrifuged at 12,000 r.p.m. (Beckman JS-13 rotor) for 30 min. The final nuclear pellet was resuspended in TETK buffer. Incubation was carried out immediately after the preparation of the nuclei. Fraction II, in the absence of fraction I, was incubated with nuclei and showed initial binding which was then reduced to insignificant levels after 20 min (Fig. 3*a*). In contrast, the nucleus-bound hormone showed a sharp increase when the nuclei were incubated in the presence of fractions I and II. An increase in oestradiol binding to DNA-cellulose¹³, dependent on the concentration of fraction I, was observed when DNA-cellulose suspensions were mixed with a constant

Fig. 5 Sedimentation behaviour of the active factor in fraction I that stimulates the binding of fraction II-oestradiol complex to DNA-cellulose. An aliquot of fraction I was centrifuged on a 5–20% linear sucrose gradient (in 0.3 M KCl-TETK buffer) at 45,000 r.p.m. for 16 h. The fractions collected from the punctured tube were assayed for the presence of the receptor activation factor by incubating with DNA-cellulose (5 µg DNA), fraction II (10 µg protein) and 10 nM ³H-oestradiol ± 1 µM DES at 30 °C for 30 min. The specific binding was calculated as described in Fig. 3 legend.

amount of fraction II protein and varying doses of fraction I (Fig. 3b). There was no specific binding of oestradiol to DNA-cellulose in the absence of fraction I, irrespective of large increases in the amount of fraction II protein added. Pretreatment of fraction I with trypsin destroyed its ability to cause binding of fraction II to DNA-cellulose (data not shown).

Native calf thymus DNA was incubated with fraction II and ³H-oestradiol in the presence or absence of fraction I (Fig. 4) and the samples were layered over 5–20% sucrose density gradients and centrifuged at 45,000 r.p.m. for 2 h. Gradient fractions were examined for the binding of oestradiol-fraction II complex to DNA—no binding was observed when the incubation was carried out in the absence of fraction I but when fraction I was mixed with fraction II the labelled complex co-sedimented with the DNA.

The ability of fraction I to effect the binding of fraction II-oestradiol complex to DNA-cellulose was the basis of an assay for the detection of the active factor in fraction I. An aliquot of fraction I was subjected to density-gradient centrifugation on 5–20% sucrose gradients at 45,000 r.p.m. for 16 h. The fractions were individually incubated with known amounts of fraction II protein, DNA-cellulose and 10 nM ³H-oestradiol either in the presence or absence of 1 µM DES. A macromolecular fraction that sedimented at 3S (2.9S) was shown to stimulate oestradiol-fraction II binding to DNA-cellulose (Fig. 5)—we call this protein the receptor activation factor.

These data show that a cytosol protein which does not bind oestradiol is involved in the activation of the oestrogen receptor. This activation factor causes a 4 to 5S shift in the sedimentation coefficient of the receptor and allows it to bind to DNA and uterine nuclei. It is possible that the basic protein identified by Bresciani *et al.*¹⁴ as an intranuclear acceptor for oestrogen receptors is similar to the receptor activation factor, which is tightly bound to chromatin following nuclear translocation. There is an obvious analogy between the activation factor and factors which stimulate RNA polymerase activity in other

eukaryotic systems^{5–11}. As suggested by Thrower *et al.*⁴, it is possible that the function of the receptor is to translocate this factor to the nucleus, where it stimulates transcriptional events.

***onc* sequences (*v-fes*) of Snyder-Theilen feline sarcoma virus are derived from noncontiguous regions of a cat cellular gene (*c-fes*)**

G. Franchini*, J. Even†, C. J. Sherr† & F. Wong-Staal*

* Laboratory of Tumor Cell Biology and † Viral Pathology Section, National Cancer Institute, NIH, Bethesda, Maryland 20205, USA

Type C sarcoma viruses are genetic recombinants containing portions of replication-competent helper viruses linked to sarcoma virus-specific sequences (generically designated *onc* genes) which are thought to be required for acute fibroblast transformation^{1–4}. The *onc* elements of different avian and mammalian sarcoma viral isolates are each homologous to subsets of cellular DNA sequences which have no well-defined role in normal cells^{5–8}. Because of the lack of significant homology between helper viral genes and cellular *onc* sequences^{1–9}, the recombinational mechanisms which facilitate the formation of sarcoma viral genomes remain unclear. In Moloney murine sarcoma virus, viral *onc* (or *v-mos*) and cellular *onc* (or *c-mos*) sequences exhibit complete and uninterrupted homology as determined by heteroduplex and restriction enzyme analyses of molecularly cloned DNA⁹. By contrast, the cellular counterparts of the *onc* elements of Rous sarcoma virus (G. Cooper and R. Parker, personal communication), avian erythroblastosis virus (B. Vennstrom, personal communication), Abelson leukaemia virus (D. Baltimore, personal communication), Harvey sarcoma virus (E. Scolnick, personal communication) and simian sarcoma virus (R. Gallo, personal communication) are now known to contain intervening sequences which do not appear in the respective viral genomes. Here we report the use of the Southern blot technique¹⁰ to examine cat cellular DNA sequences (*c-fes*) homologous to the *onc* gene (*v-fes*) of Snyder-Theilen feline sarcoma virus (ST-FeSV)¹¹. We used cloned DNA 'probes' containing defined portions of the ST-FeSV genome to show that *v-fes* sequences originate from at least four noncontiguous sequences in cat cellular DNA, separated from each other by intervening sequences.

The unintegrated DNA intermediates of ST-FeSV and feline leukaemia virus (FeLV) (subgroup B) helper virus have been previously cloned in a bacteriophage λ vector and characterized in detail¹². The *v-fes* sequences of ST-FeSV are ~1.3 kilobase pairs long and include at least three cleavage sites for the restriction endonuclease *Pst*I. An additional *Pst*I site is located to the right and demarcates a 140-base fragment which includes the 3' junction of *v-fes* and FeLV-derived sequences (Fig. 1). The two larger *Pst*I fragments, each ~0.5 kilobase pairs long, we have designated *S_L* and *S_R* as they represent the left and right portions of the *v-fes* region in 5' to 3' orientation with respect to viral RNA. *S_L* and *S_R* DNA fragments were partially purified by electroelution from agarose gels and separately subcloned into the ampicillin-resistance gene of the plasmid vector pBR322. The recombinant plasmids were identified by replica-plating and colony hybridization techniques, grown in an *Escherichia coli* host, and their DNA extracted using methods described elsewhere¹³. Purified plasmids containing *S_L* or *S_R* were labelled with ³²P by nick-translation¹⁴ and hybridized by the Southern blot technique¹⁰ to restricted DNA obtained from tissues of specific pathogen-free domestic cats (Liberty Laboratories).

The restriction endonucleases *Hind*III, *Eco*RI and *Bgl*II do not recognize cleavage sites within *v-fes* sequences¹⁵ and when cat DNA was cleaved with these enzymes, single *c-fes*-containing fragments of 9.4 (*Hind*III), 13 (*Eco*RI) and 22 (*Bgl*II) kilobase pairs were detected with both radiolabelled probes (Fig. 2, lanes 1–3). The *S_L* and *S_R* portions of *c-fes* must therefore be sited at a discrete genetic locus (maximal complexity = 9.4 kilobase pairs).

If sequences homologous to the *S_L* probe were contiguous in cat cellular DNA, cleavage with *Pst*I should yield a single hybridizable DNA fragment equal in length to that of *S_L* itself (~500 bases). However, *Pst*I generated two fragments of 1.8 and 0.7 kilobase pairs which were detected with the *S_L* probe (Fig. 2, lane 6 and Fig. 3, lane 1). The combined length of these fragments (2.5 kilobase pairs) is at least 1.9 kilobase pairs longer than the *S_L* sequence itself which indicates that the *c-fes* domain related to *S_L* must contain 1.9 kilobase pairs of intervening sequences that include a *Pst*I site absent in *v-fes*. To orientate the 0.7- and 1.8-kilobase pair fragments from 5' to 3' with respect to viral RNA, we performed co-digestion analyses with enzymes that recognize single, asymmetric sites within the *v-fes* *S_L* region. Figure 1 shows that *Kpn*I and *Sac*I each cleave at opposite ends of the *S_L* region within 0.1 kilobase pairs of the *Pst*I termini. Co-digestion of cat DNA with *Kpn*I and *Sac*I yielded a 2.3-kilobase pair fragment which hybridized strongly to the *S_L* probe (Fig. 3, lane 9). The length of this fragment was

~0.2 kilobase pairs shorter than the total complexity of the *c-fes* *S_L* domain (2.5 kilobase pairs) which demonstrates that no *Kpn*I or *Sac*I sites can be detected in the region(s) containing intervening sequences. Digestion with *Kpn*I reduced the length of the 0.7-kilobase pair *Pst*I fragment by <0.1 kilobase pairs (Fig. 3, lanes 1, 2), and *Sac*I reduced the length of the 1.8-kilobase pair *Pst*I fragment by a similar extent (Fig. 3, lanes 1, 3). Thus, the 0.7-kilobase pair *Pst*I fragment is located at the 5' end of the 1.8-kilobase pair *Pst*I fragment (Fig. 1).

The *S_R* probe also hybridized to a 1.7-kilobase pair *Pst*I fragment which is about three times more complex than the *S_R* sequences themselves (Fig. 2, lane 7). No enzymes tested so far have cleaved the *S_R*-related 1.7-kilobase pair *Pst*I fragment. The simplest model places an additional 1.2 kilobase pairs of intervening sequences at the centre of the *c-fes* *S_R* domain as shown in Fig. 1. These data suggest that the complexity of the *c-fes* domain detected with both probes is 4.2 kilobase pairs (*S_R*, 1.7 and *S_L*, 2.5 kilobase pairs).

Co-digestion experiments and hybridization with the two probes allowed the sites of cleavage for *Hind*III and *Eco*RI to be positioned with respect to the defined *Sac*I and *Kpn*I sites in *c-fes* (data not shown). Each of these enzymes recognizes sites which are comparatively distant from the *c-fes* region. Other positions for *Sac*I and *Kpn*I cleavage in flanking DNA sequences were assigned by similar procedures (see Fig. 2, lanes 4, 5 and Fig. 3, lanes 7, 9 for *Sac*I and *Kpn*I data). In contrast to *Hind*III and *Eco*RI, *Bgl*II recognizes a cleavage site close to the 5' end of the *c-fes* *S_L* domain. Co-digestion with *Sac*I and *Bgl*II generates a 2.6-kilobase pair fragment detectable with the *S_L* probe (Fig. 3, lane 8), which positions the *Bgl*II site within 0.3 kilobase pairs from the left-hand *S_L* *Pst*I site (Fig. 1).

Although *v-fes* lacks sites of restriction for *Bam*HI (ref. 15), cleavage with this enzyme yielded two DNA fragments of 5.2 and 2.8 kilobase pairs which were detected with the *S_L* probe (Fig. 2, lane 8 and Fig. 3, lane 5). The 2.8-kilobase pair fragment alone was seen using the *S_R* probe (Fig. 2, lane 9) which indicates that *Bam*HI, like *Pst*I, recognizes a single site within the *c-fes* *S_L* domain. As expected, the left-hand 5.2-kilobase pair *Bam*HI fragment was cleaved by *Bgl*II to produce a 2.3-kilobase pair *S_L*-related fragment, thus positioning the *Bam*HI site (Fig. 3, lanes 5, 6). Co-digestion of cat DNA with *Bam*HI and *Pst*I was therefore expected to result in the digestion of the 1.8-kilobase pair *Pst*I fragment to two fragments of ~1.4 and 0.4 kilobase pairs. If the 1.4-kilobase pair *Pst*I–*Bam*HI fragment thus produced contained only intervening sequences, we would not expect to detect it with the *S_L* probe. Surprisingly, this fragment was readily visualized (Fig. 3, lane 4) which indicates that at least

Fig. 1 Restriction endonuclease map of cat cellular DNA sequences containing regions of homology to *v-fes*. The top line represents the linear ST-FeSV provirus from 5' to 3' with respect to viral RNA. Subcloned *Pst*I fragments representing 80% of *v-fes* (box) and labelled *S_L* and *S_R* were used to map homologous sequences in restriction fragments of cat cellular DNA. The middle line shows the sequences homologous to *S_L* and *S_R* probes with *c-fes*. The complexity and location of the central hybridizing sequence (stippled area) at the left of the *Bam*HI site remain uncertain. Sequences homologous to *v-fes* *S_R* shown in black contain at least one set of intervening sequences no longer than 1.2 kilobase pairs. The bottom diagram shows non-inclusive sites of restriction in cat DNA sequences flanking *c-fes*. Only sites which can be assigned using *S_L* and *S_R* probes are indicated.

Fig. 2 Detection of sequences in cat cellular DNA related to *v-fes* S_L and S_R probes. DNA (30 μ g per lane) was digested and hybridized in conditions described by Wahl *et al.*²⁵. The sizes of fragments (in kilobase pairs, kb) were determined from the positions of restriction fragments of adenovirus type 2 DNA (Bethesda Research Laboratories) used as internal digestion standards. Lanes 1-3 show results from a 0.8% gel using the S_L probe; identical results were obtained with S_R or with a mixture of S_L and S_R probes. Lanes 4, 5, 8 and 9 show results from 1.4% gels and lanes 6 and 7 from a 1% gel. The enzymes used are indicated above the lanes and the probes are noted below.

some S_L -related sequences map within this region. The S_L -related domain of *c-fes* must therefore contain at least two noncontiguous segment of intervening sequences (Fig. 1).

The presence of a *SalI* site within S_L sequences suggested that it might be possible to localize the central hybridizing sequence more precisely within the *c-fes* S_L domain. However, co-digestion of cat DNA with *SalI* and several other enzymes failed to demonstrate a *SalI* site in *c-fes*. Although we favour the possibility that the *SalI* hexanucleotide recognition sequence is methylated, we cannot exclude the possibility that the *SalI* site is in fact absent.

Thus, cloned subgenomic DNA fragments representing ~80% of the ST-FeSV sarcoma virus-specific sequences can be used to detect a discrete *c-fes* locus in the cellular DNA of normal domestic cats. This locus (estimated complexity of S_L and S_R , 4.2 kilobase pairs) is significantly more complex than *v-fes* itself and contains at least three subsets of intervening sequences which lack homology to the viral *onc* gene. Although the presence of intervening sequences is suggested by the complexity of the *c-fes* locus alone, our positioning of the intervening sequences is based on the simple assumption that the restriction sites in *v-fes* are retained in *c-fes*. In the case of *v-fes* S_L sequences where five sites for restriction endonuclease cleavage have been assigned, at least four (and possibly all) of these seem to be retained in the *c-fes* S_L domain. Two additional

sites for *BamHI* and *PstI* also appear within the *c-fes* S_L domain and map within two different intervening sequences. Because no sites other than those for *PstI* have been assigned within the *v-fes* S_R region itself or within the *c-fes* S_R domain, we cannot determine whether the S_R domain includes one or more subsets of intervening sequences, nor can we exclude the possibility that a *PstI* site in *v-fes* has no homologue in *c-fes*. Finally, we have not positioned the sequences in cellular DNA that are homologous to the extreme 5' end (0.2-0.4 kilobase pairs) and 3' end (0.1 kilobase pairs) of *v-fes* for which specific probes are unavailable. The close proximity of the *BglII* site to the 5' end of the S_L domain raises the possibility, however, that this site maps within yet another *c-fes* intervening sequence. Thus, it seems likely that *c-fes* is indeed more complex than our minimal estimate of 4.6 kilobase pairs (S_L , S_R and unmapped terminal *v-fes* sequences).

The organization of the *c-fes* gene raises critical questions concerning the formation of feline sarcoma viral genomes. ST-FeSV encodes a polyprotein of 85,000 molecular weight^{16,17} which shows protein kinase activity^{18,19} and is specified in part by *v-fes* sequences¹⁵. Transformation-defective ST-FeSV mutants²⁰ synthesize altered polyproteins that have no kinase activity (M. Barbacid, S. K. Ruscetti, L. Donner and C. J. Sherr, unpublished data) which strongly suggests that expression of the *v-fes* encoded function is required for ST-FeSV-induced transformation. If, like the Rous sarcoma viral system²¹⁻²³, the cellular *onc* gene codes for a protein which is immunologically and functionally related to that encoded by ST-FeSV, the intervening sequences would presumably represent noncoding regions of the cellular gene (introns) which would be deleted after formation of the primary transcripts. Although formation of recombinant FeSV genomes could involve cross-over between a helper DNA provirus and *c-fes* DNA sequences, the retention of only the putative coding regions (exons) would then have to involve a process of systematic DNA deletions analogous to RNA splicing events. Alternatively, spliced *c-fes* mRNA molecules could be packaged in helper viral particles, copied by reverse transcription into DNA in another round of infection, and be subsequently recombined with proviral DNA. Whatever the mechanism, the formation of transforming sarcoma viruses would at least require the retention of the critical coding sequences of the cellular gene. As the Gardner-Arnstein (GA) strain of FeSV²⁴ has also acquired sequences homologous to *v-fes*⁸, it will be of interest to see if the differences between the ST and GA strains^{16,17} reside in the sarcoma virus-specific or helper virus-derived regions of these genomes.

We thank Dr William McClements for his advice in preparing the plasmid subclones, Dr Robert C. Gallo for helpful criticisms and support, K. Gorse for assistance with the experiments, and the many investigators for communication of the unpublished results.

Fig. 3 Co-digestion experiments done using the S_L probe. The enzymes used are indicated above the lanes and the lengths of the fragments in kilobase pairs are shown at the sides.

Causes of more frequent deletions than insertions in mutations and protein evolution

Wilfried W. de Jong* & Lars Rydén†

* Department of Biochemistry, University of Nijmegen, 6525 EZ Nijmegen, The Netherlands

† Institute of Biochemistry, Biomedical Center, University of Uppsala, S-751 23 Uppsala, Sweden

Deletions and insertions of base pairs in DNA, jointly called gap events, are one of the major sources of evolutionary change at the molecular level. On the basis of very limited data, Fitch¹ has suggested that deletions might be expressed more often than insertions in proteins. We have examined the presently available homologous protein sequences, and observed that in the course of evolution, deletions of amino acids have indeed occurred about four times more frequently than insertions. An even higher preponderance of deletions over insertions (ten times or more) is found in recent spontaneous and induced mutants of genes or proteins. We propose here a mutational mechanism to explain this predominance of deletions.

Gap events are relatively rare in protein evolution, and mainly occur in the early stages of divergent evolution of duplicated genes². A study of gap events in the evolution of a protein requires a phylogenetic tree that allows us to differentiate between insertions and deletions. This means that the gap events must be located far enough from the root of the tree, and that the sequence homology must be sufficiently close to allow a reasonably unambiguous placement of gaps in the aligned sequences. In trees of distantly related proteins the large number of point mutations usually does not allow an unambiguous positioning of the gaps in the tree, whereas trees of closely related proteins have most of the gaps at the root. Therefore rather few protein families meet the above conditions for assignment of deletions or insertions.

We have, however, been able to trace nine families, comprising a total of 178 sequences, which are useful in this respect (Table 1). They contain a total of 37 gaps representing, on average, 2.2% of the total number of mutations. The figure

varies from less than 1% for trees of closely related sequences to 5% for more distantly related ones. As silent mutations are not included, the percent of gaps among the accepted changes must be even lower at the DNA level. Of the 37 gaps, 23 involve a single amino acid residue, 7 involve 2 residues and the remaining gaps involve 3 and 5 residues. The data show a fourfold excess of deletions over insertions. This preponderance of deletions in protein evolution suggests either that deletions are more readily accepted than insertions, or that there is a higher incidence of deletions than insertions at the DNA level. The former possibility is difficult to assess, but the latter explanation can be tested by examining gap events among mutant proteins and genes which are not constrained by selective pressure at the protein level.

Most informative in this respect are the abnormal human haemoglobins, of which a total of 204 different variants have been characterized³. Among these are 10 deletions, varying in length from one to five residues, and only a single insertion, of three residues (Table 2). Although numerous mutants of prokaryotic and eukaryotic genes and proteins are known, only very few have been characterized at the level of the nucleotide or amino acid sequence. However, large collections of mutants of the *lac I* gene and the λ -receptor propeptide gene of *Escherichia coli* have been analysed by nucleotide sequencing (Table 2). These studies show that >90% of the gap events are deletions, and that the gaps represent at least some 50% of the mutations when selection is absent.

We have also included (Table 2) the recently sequenced haemoglobin pseudogenes, which were probably functional genes up to a point where frameshift mutations and other changes prevented their expression, after which the acceptance of mutations in such pseudogenes was no longer constrained by selective forces at the protein level, and they were more free to accumulate deletions and insertions than coding genes. In the pseudogenes for which sequences have been published, 14 deletions and 7 insertions can be demonstrated with certainty. Comparison of other published sequences of non-coding DNA reveals that deletions, insertions and small duplications are indeed the most frequent mutational events in unconstrained sequences⁴, but does not allow any distinction between deletions and insertions.

The data show that the surplus of deletions and the preponderance of gaps among the mutations are inherent in the mutational process and that selection at the protein level reduces their proportion. Possible mechanisms for the creation of gaps include unequal cross-over between homologous genes^{1,5}, and,

Fig. 1 Mutational model to explain the excess of deletions. Breakage of a DNA strand is followed by gap formation and looping-out of bases by slip mispairing; *a* and *b* represent the repair pathways resulting in deletion and addition of bases, respectively, according to the original Streisinger model⁹. If, as shown in *a'* and *b'*, the extrahelical loops are trimmed off by single-strand specific nuclease an excess of deletions follows. The removal of extrahelical bases can occur concomitantly with or after the repair process, but should take place before the replication process starts.

Table 1 Gap events in evolving proteins

Protein family	No. of sequences	No. of positions	No. of deletions	No. of insertions	No. of undecided gaps	Gaps as % of mutations	Ref.
Vertebrate myoglobins	31	153	1	0	0	0.5	15
Vertebrate pancreatic ribonucleases	43	123	2	0	2	1.2	16
Vertebrate α -crystallin A chains	43	173	2	0	0	2.0	17
Eukaryotic cytochrome c	6	101	2	0	2	2.4	
Eukaryotic and cyanobacterial plastocyanins	12	102	1	0	1	1.3	18
Vertebrate phospholipases	8	126	6	3	2	4.7	18
Mammalian lipotropins	4	93	0	1	0	3.3	18
Mammalian proinsulins	7	87	3	0	0	4.9	18
Vertebrate globins	24	146	7	2	0	2.5	18
Sum	178		24	6	7	2.2	

Phylogenetic trees, if not published, were constructed for each protein family¹⁴, and the number of substitutions, deletions, insertions and undecided gaps counted. Gaps were counted as a 21st amino acid. In the calculation of mutations the termini of the aligned polypeptide chains counted from the shortest one or a penultimate gap in the longer one were excluded. This was because gaps in this region might be due to base substitutions involving initiation or termination codons, and not to deletions or additions of bases, and furthermore, at penultimate positions the assignment of gaps or substitutions may be arbitrary. Several protein families that actually contain considerable numbers of gap events are not included because their cladistic relationships are difficult to assess (all viral and prokaryotic sequences; snake neurotoxins and cytotoxins; immunoglobulins) or their alignment too ambiguous (fibrinopeptides).

Table 2 Gap mutations in mutant genes or proteins subject to no selection or only partial selection

Gene or protein	No. of mutants	Deletions	Insertions	Gaps as % of total mutations	Type of selection	Ref.
Human haemoglobin variants	204	10	1	5	Functional or sublethal protein	3
<i>E. coli lac I</i> gene	140	20*	1†	46‡	No selection	10
<i>E. coli</i> λ -receptor protein gene	27	13		48	No selection	19
<i>Neurospora crassa</i> glutamate dehydrogenase, revertants of am6 mutant	14	14		100§		20
Haemoglobin pseudogenes :						
mouse α -3		8	6	18	Possibly no selection after expression ceased	21
human $\psi\alpha$ 1		3		3		22
rabbit $\psi\beta$ 2		2		3		23
goat β^x		1	1	4		24

* One of these mutations appeared 18 times in the collection, but is counted only once (hotspot mutation).

† This mutation appeared 78 times in the collection but is counted only once (same hotspot as in *). It reverted with a frequency of 10^{-5} .

‡ This is a low estimate because not all mutants were characterized. If the multiple hotspot mutations are included it increases to >80%.

§ All 14 revertants analysed were found to be deletions, although the am6 mutant itself is thought to be a one-base insertion.

|| Only the positions corresponding to the expressed portions of the functional genes are considered.

in some cases, changes at intron-exon junctions⁶⁻⁸. Most gaps, however, can probably be adequately explained by the Streisinger model⁹ in which DNA strand breakage is followed by 'slipped mispairing' and consolidation of the mispaired configuration by DNA repair. Such 'slippage' would be favoured by tandemly repeated nucleotide sequences; insertions and deletions frequently (but not always) occur in repeated sequences^{5,9-11}. In agreement with this model, it has been found that most gap mutations produced by UV light, arise during excision repair⁵.

The Streisinger model explains deletions equally well as insertions, and does not *a priori* lead one to expect a preponderance of either. However, a simple extension of this model can explain an excess of deletions. In the Streisinger model the slipped mispairing after strand breakage results in the looping-out of a number of bases. Such transient extrahelical loops should be vulnerable to single-strand specific nuclease action¹², and might be trimmed off (and the resulting broken strand ligated) before replication occurs. Such a process would decrease the frequency of insertions and favour the occurrence of deletions (Fig. 1). Similarly, the recently proposed mechanism for the generation of deletions by slipped mispairing during replication¹¹ could contribute to the scarcity of insertions.

A higher incidence of deletions than insertions during protein evolution should lead to a gradual decrease in the lengths of

polypeptide chains—this seems to be true for the insulin C peptide¹³, and the ancestral globin chain was probably longer than the contemporary vertebrate haemoglobin and myoglobin chains (excluding terminal extensions)². However, the shortening effect of the deletion events is not dramatic: they are very rarely accepted in proteins with stabilized functions, compared with the frequency of amino acid substitutions.

Studies both *in vivo*^{1,2} and *in vitro*^{1–5} have shown that substituted benzimidazoles inhibit the stimulation of acid secretion produced by dibutyryl cyclic AMP and histamine. Furthermore, the results differ from those produced by H_2 antagonists and anticholinergic agents in that the inhibition is not competitive, and the site of action is intracellular and peripheral to that of dibutyryl cyclic AMP. To investigate the biochemical mechanism of action of substituted benzimidazoles, one such compound, H 149/94 (2-[2-(3-methylpyridyl-methyl)-sulphonyl]-5-methoxycarbonyl-6-methylbenzimidazol), has been tested either directly on an ($H^+ + K^+$)ATPase isolated from pig and human gastric mucosa or on the function of this enzyme in gastric glands isolated from rabbit and human gastric mucosa. ($H^+ + K^+$)ATPase^{6,7}, which has only been found at the secretory surface of the parietal cell⁸, catalyses a one-to-one exchange of protons and potassium ions^{9–11}. It is possibly the proton pump within the gastric mucosa, and may thus be the terminal or one of the terminal steps of the acid secretory process^{12,13}. We show here that H 149/94 inhibits ($H^+ + K^+$)ATPase, which may explain its inhibitory action on acid secretion *in vitro* and *in vivo*. Because of the unique distribution and properties of the ($H^+ + K^+$)ATPase, the inhibitory action of H 149/94 on this enzyme may be a highly selective clinical means of suppressing the acid secretory process.

Isolated gastric glands have been shown to respond to a number of different secretagogues and inhibitors^{5,14,15}. Secretagogues such as dibutyryl cyclic AMP and K^+ stimulate acid secretion intracellularly, presumably at a site close to the ($H^+ + K^+$)ATPase^{16–18}. In contrast, histamine and acetylcholine have a site of action further removed from the enzyme^{14–16,19}. This may be either extracellular or at an earlier stage in the sequence of events leading to acid secretion, possibly reflecting the physiological role of such agonists in the control of acid secretion. Thus, isolated gastric glands, used in conjunction with specific cholinergic and histaminergic antagonists, provide a useful experimental model for determining the site of action of drugs influencing acid secretion, independently of hormonal and

Fig. 1 The inhibitory action of H 149/94, atropine and cimetidine on ^{14}C -AP accumulation induced by different agonists in isolated gastric glands from rabbit mucosa. The preparation and incubation of the isolated glands was essentially as described elsewhere^{14,15} except that the incubation volume was reduced from 3 to 0.2 ml and the amount of glands also reduced proportionally. The glands were suspended in a physiological buffer solution containing rabbit albumin (2 mg ml⁻¹), glucose (10 mM) and ^{14}C -AP (0.25 μCi and 8 μmol per incubation), and incubated in a shaking bath for 90 min at 37°C. After the incubation the glands were spun down at 2,000g for 2 min. The supernatant was removed and the wet and dry weights of the pellet determined. The dried pellets were solubilized in 1 ml Soluene. Dimilume (10 ml) was added and the radioactivity then counted. H 149/94 was dissolved in methanol. All incubations contained 1% methanol, which had no influence on the ^{14}C -AP ratio. All other added substances were dissolved in the physiological buffer solution. In the experiments with high [K^+] (0.1 M), the glands were washed three times with an incubation medium in which KCl (0.1 M) had been substituted for NaCl (0.1 M). The respective control values without antagonist have been set to 100%. The results are mean $\pm$ s.e. of 6–8 observations. A statistically significant difference ($P < 0.05$ Student's *t*-test) from control is denoted by an asterisk.

nervous influence. Although the rate of acid secretion cannot be measured quantitatively with isolated glands, the acid secretory response can be monitored semiquantitatively by measuring the uptake of a radiolabelled weak base, ^{14}C -aminopyrine (^{14}C -AP), which accumulates in the glands in proportion to the pH differences between the intraglandular acid compartments and the surrounding medium^{14,15}.

The effects of H 149/94 (10^{-4} , 10^{-6} M), cimetidine (10^{-4} M) and atropine (10^{-4} M) on ^{14}C -AP accumulation in rabbit gastric glands stimulated by histamine, dibutyryl cyclic AMP and K^+ are shown in Fig. 1. Atropine had no inhibitory effect in the presence of any agonist. Cimetidine inhibited the response to histamine (54 μM) but had no effect in the presence of dibutyryl cyclic AMP (1 mM) or K^+ (0.1 M). H 149/94 produced dose-dependent inhibition ($ED_{50} \sim 10^{-5}$ M) of ^{14}C -AP accumulation irrespective of the agonist used. The presence of potassium is an absolute requirement for acid secretion, presumably reflecting its involvement in the exchange process catalysed by ($H^+ + K^+$)ATPase^{17,18}. The marked inhibition of K^+ -induced ^{14}C -AP accumulation produced by H 149/94 therefore strongly supports the view that this compound interferes with acid secretion at or close to the enzyme, the probable terminal step of the secretory process. The lack of effect with cimetidine and atropine suggests a more distant site of action of these compounds.

Fig. 2 Effect of H 149/94 on proton transport catalysed by the ($H^+ + K^+$)ATPase. Gastric membranes were prepared from pig stomach by differential and zonal density gradient centrifugation²⁰. The vesicle fraction ($\sim 40 \mu\text{g ml}^{-1}$) was equilibrated at 4°C overnight in the following medium: 2 mM PIPES-Tris, pH 6.7, 150 mM KCl, 2 mM MgCl_2 with or without H 149/94 at concentrations of 10^{-4} , 10^{-5} , 10^{-6} M as indicated. H 149/94 was dissolved in methanol. All incubations contained 1% methanol, which had no influence on the assay. At the start of the experiment $20 \mu\text{M}$ acridine orange was added to the sample and the reaction started by the addition of 0.6 mM ATP (disodium salt). The acridine orange absorbance change was monitored in an Aminco DW-2 spectrophotometer in the dual-beam mode set at 490 and 530 nm.

To explore the possibility that H 149/94 interacts directly with ($H^+ + K^+$)ATPase, the enzyme was isolated from pig stomach by differential and zonal gradient centrifugation²⁰. The vesicular fraction sedimenting between the 0.25 M sucrose–8% Ficoll interface was either used directly for proton transport studies, or further purified by free-flow electrophoresis and subsequent lyophilization for studies with an ATPase assay. Fresh vesicles are relatively impermeable to cations such as protons and K^+ and readily allow measurements of proton transport⁹, which can be quantified using the dye acridine orange. The control curve in Fig. 2 shows the acridine orange absorbance, when ATP is added to the K^+ -preloaded vesicles in

Fig. 3 The effects of H 149/94, atropine and cimetidine on isolated gastric ($H^+ + K^+$)ATPase from pig mucosa. The ($H^+ + K^+$)ATPase was obtained by differential and zonal density discontinuous gradient centrifugation followed by free-flow electrophoresis²⁰. ($H^+ + K^+$)ATPase activity was quantified by the K^+ -stimulated release of phosphate²². The incubation concentrations were Tris-HCl 40 mM, pH 7.4, MgCl_2 2 mM, ATP 2 mM, with or without KCl 10 mM. The enzyme ($\sim 10 \mu\text{g}$ per incubation) was preincubated with the drugs for 30 min and the time of incubation was 15 min at 37°C . H 149/94 was dissolved in methanol. All incubations contained 1% methanol, which had no influence on ($H^+ + K^+$)ATPase activity.

the absence of inhibitor. The interpretation of the control curve has been described elsewhere^{11,21} but briefly, on addition of ATP there is a rapid loss of acridine orange absorbance corresponding to transport of H^+ into the vesicle. This is followed by an increase in the absorbance produced by an outward H^+ leak, due to depletion of intravesicular K^+ . Thus, the H^+ transport signal is both ATP and K^+ dependent. In this experiment (Fig. 2) the vesicle preparation was incubated with H 149/94 at concentrations of 10^{-6} , 10^{-5} and 10^{-4} M. There was progressive inhibition of the transport signal with increasing H 149/94 concentrations—that is, proton transport was inhibited.

To test whether this inhibition of proton transport was a consequence of decreased ($H^+ + K^+$)ATPase pump activity, K^+ -ATPase activities were measured at different H 149/94 concentrations. Figure 3 shows that H 149/94 produces dose-dependent inhibition of ($H^+ + K^+$)ATPase activity in contrast to cimetidine and atropine. We therefore conclude that the inhibition of proton transport by H 149/94 (Fig. 2) corresponds to the inhibition of ($H^+ + K^+$)ATPase activity seen in Fig. 3.

Fig. 4 The inhibitory action of H 149/94 on dibutyl cyclic AMP (10^{-3} M)-induced ^{14}C -AP accumulation in human isolated gastric glands ($\square$) and P_i release catalysed by isolated human ($H^+ + K^+$)ATPase ($\blacksquare$). The mucosa was obtained from surgical biopsies taken during gastrectomy for either recurrent gastric ulcer or recurrent ulceration after previous vagotomy. The isolated glands⁵ were prepared as for the isolated gastric glands from rabbit (Fig. 1). ($H^+ + K^+$)ATPase was prepared by differential centrifugation and further purified on a discontinuous step gradient⁵. The ATPase assay was performed as for pig ($H^+ + K^+$)ATPase (Fig. 3) except that the release of radiolabelled phosphate from $[\gamma\text{-}^{32}\text{P}]\text{ATP}$ was measured²³. The results are mean $\pm$ s.e. of four observations.

H 149/94 inhibits gastric acid secretion in man (Olbe *et al.*, unpublished observation). As the therapeutic value of the compound may be its antisecretory activity in peptic ulcer patients, a series of experiments similar to those described above was performed on isolated gastric glands and ($H^+ + K^+$)ATPase obtained from gastric mucosal biopsy specimens from such patients. The results are shown in Fig. 4. H 149/94, at concentrations comparable with those found effective in the animal preparations, produced dose-dependent inhibition of both dibutyl cyclic AMP-induced ^{14}C -AP accumulation in gastric glands, and P_i release from vesicles.

Thus, these results suggest that the substituted benzimidazole, H 149/94, is an inhibitor of the ($H^+ + K^+$)ATPase and provide a mechanism for the inhibitory effects of H 149/94 on acid secretion which have been demonstrated *in vitro* and *in vivo*¹⁻⁵. Because of the unique distribution of the ($H^+ + K^+$)ATPase, the inhibitory effects of H 149/94 may offer a highly selective means of suppressing secretion for therapeutic purposes.

Location of hexane in lipid bilayers determined by neutron diffraction

Stephen H. White*†, Glen I. King*
& James E. Cain ‡§

Knowledge of the interactions of alkanes and other small hydrophobic molecules dissolved in lipid bilayers is important for understanding lipid–protein interactions in membranes¹, the microscopic properties of solutions^{2,3} and the mechanism of anaesthesia^{4–6}. An essential element for describing these interactions is the distribution of the molecules across the thickness of the bilayer. Studies of black lipid films^{1,2,7–9} strongly suggest that dissolved alkanes are located primarily in the centre of the bilayer. Recent X-ray and neutron diffraction and thermodynamic measurements on lipid dispersions and oriented lipid multilayers are consistent with this view^{10–12}. We present here the first direct evidence for this hypothesis obtained from neutron diffraction studies of oriented dioleoyl lecithin (DOL) multilayers containing deuterated hexane introduced using the vapour phase. The hexane is found mainly in a zone 10 Å wide in the centre of the bilayer. We have also estimated the amount of hexane in the bilayers and the free energy of transfer from pure hexane to bilayer. Our numbers are considerably different from those reported by Simon *et al.*¹³ for the interaction of hexane with DOL liposomes. The differences may be due to difference in water activity and bilayer curvature¹⁴.

The neutron scattering length of the hydrogen nucleus is -0.38×10^{-12} cm whereas for the deuterium nucleus it is $+0.65 \times 10^{-12}$ cm (ref. 15). Consequently, the introduction of deuterated alkane into a bilayer containing non-deuterated acyl chains produces large changes in the neutron scattering density of the hydrophobic core of the bilayer. The location of the alkane can be established in the following way. Diffraction measurements are performed on lipid bilayers containing hydrogenated alkane

(H-alkane) and on bilayers containing deuterated alkane (D-alkane) at the same concentration. The resulting structure factors are used to construct neutron scattering density profiles $\rho_H(x)$ and $\rho_D(x)$ of the bilayers containing, respectively, H-alkane and D-alkane. Subtraction of the two profiles yields the difference scattering density profile $\Delta\rho(x) = \rho_D(x) - \rho_H(x)$. The contribution made to each profile by the water, polar groups and acyl chains are the same and cancel out. Therefore, $\Delta\rho(x)$ represents the distribution of the deuterated alkane across the thickness of the bilayer. This general method¹⁶ has been used to locate water^{17,18}, cholesterol¹⁸ and specific atoms on phosphatidylcholine molecules^{19–21} in lipid bilayers.

Here we have measured the distribution of *n*-hexane in DOL bilayers at relatively low hexane concentrations. Hexane was chosen for this initial study of alkane–bilayer interactions because (1) it has a high vapour pressure and can be introduced into the bilayer via the vapour phase in equilibrium conditions; (2) the vapour pressure can be controlled with hexane/hexadecane mixtures whose thermodynamic properties are well

Fig. 1 Diffraction patterns collected at the High Flux Beam Reactor at Brookhaven National Laboratory of the lamellar reflections of DOL multilayers in the presence of deuterated hexane (a) and hydrogenated hexane (b). Both patterns show four orders of diffraction ($h=4$) as recorded by a two-dimensional detector in fixed position as the sample was rotated in 0.1° steps through the Bragg angle with respect to the incident beam. The diffraction patterns were the typical lamellar type with a mosaic spread of 0.1 – 0.4° . The typical d -spacing was 48 Å. The sample was oriented on a quartz slide sealed in an aluminium chamber (temperature 22.5°C). RH was maintained at 66% with a saturated sodium nitrite solution ($100\% \text{H}_2\text{O}$, $0\% \text{D}_2\text{O}$). The vapour pressure (P) of hexane was fixed at 40 mm Hg with a hexane/hexadecane mixture. $P = X_H^m P_0$ where X_H^m is the mole fraction of hexane in the mixture (0.3 in this case) and P_0 is the vapour pressure of pure hexane (134 mm Hg, 22.5°C). The sample came into equilibrium with the hexane vapour within 2 h as shown by unchanging diffraction patterns.

known²²; (3) thermodynamic information is available on the hexane-DOL interaction in liposomes¹³ and similar information can be obtained for the oriented multibilayer system used here; and (4) hexane is an anaesthetic agent²³.

DOL multilayers were deposited on a quartz slide by evaporation from a 1:1 chloroform/methanol solution and mounted in the neutron beam in a sealed aluminium container. The DOL had been purified by thick-layer chromatography and great care was taken to insure that all the solvent used in depositing the sample had been removed. The experiments were performed at 22.5 °C and 66% relative humidity (RH) maintained by a saturated aqueous solution of sodium nitrite. The vapour pressure, P , of the hexane was controlled by hexane/hexadecane mixtures which behave nearly ideally so that $P = X_H^m P_0$ where P_0 is the vapour pressure of pure hexane (134 mm Hg at 22.5 °C) and X_H^m is the mole fraction of hexane in the mixture. X_H^m ranged from 0 to 0.3 for these experiments. The hexane activity (X_H^m) required for narcosis in mice is 0.13 at 37 °C (ref. 23).

Typical uncorrected $I(\theta)$ curves collected from DOL multilayers in the presence of hexane are shown in Fig. 1. The upper curve (a) is for D-hexane and the lower curve (b) for H-hexane. In both cases, $X_H^m = 0.3$. The two $I(\theta)$ curves are clearly different due to the difference in scattering density of H- and D-hexane. As shown in Fig. 2, the structure factors derived from such data were accurately a linear function of the percentage of D-hexane in the hexane phase. The phases for the first four orders for $X_H^m = 0.3$ are -, -, +, - and are the same as for

Fig. 2 Structure factors $F(h)$ for DOL multilayers in the presence of hexane vapour as a function of the per cent D-hexane in the vapour phase (temperature 22.5 °C, RH = 66% [100% H₂O, 0% D₂O], $X_H^m = 0.3$ [$P = 40$ mm Hg]). $F(h) = s(h) (I_h)^{1/2}$ where I_h is the intensity corrected for background and sample-beam intersection and $s(h)$ is the correct phase assignment (+1 or -1). The Lorentz correction has also been applied. The $F(h)$ values are linear, justifying the use of the difference Patterson deconvolution method^{16,25} to establish the phase assignment for each value of F . There were no changes in phase as X_H^m varied from 0 to 0.3. The figure shows the phases to be the same for D-hexane and H-hexane in this range. The phase assignments for the first four orders are -, -, +, -.

$X_H^m = 0$. These phases agree with assignments by others for dipalmitoyl lecithin¹⁷, dipalmitoyl lecithin-cholesterol¹⁶ and egg lecithin-cholesterol¹⁸.

Figure 3a shows the neutron scattering density profiles $\rho_D(x)$ and $\rho_H(x)$ for DOL bilayers containing, respectively, D-hexane (curve D) and H-hexane (curve H) at $X_H^m = 0.3$. The H-hexane profile has the typical appearance expected of bilayers and is essentially identical to profiles of hexane-free bilayers (not shown). This result is consistent with the findings of Franks and Lieb¹¹ on lecithin/cholesterol bilayers containing cyclopropane—the alkanes at moderate concentrations have no significant effect on the gross structure of the bilayer. However, the presence of alkane in the bilayer is clearly shown by the D-hexane profile. Note that the methyl trough in the centre of the bilayer has been 'filled in' due to the presence of the D-hexane in the bilayer centre. This is shown more dramatically in Fig. 4 in which difference profiles $\rho_D(x) - \rho_H(x)$ are plotted for $X_H^m = 0.05, 0.10, 0.20$ and 0.30. These profiles unambiguously demonstrate that the hexane is largely confined to the centre of the bilayer and that the amount of hexane in the centre depends directly on hexane vapour pressure.

A surprising finding is that the d -spacing of the samples does not depend, within the instrumental sensitivity (± 0.4 Å), on the hexane vapour pressure. Consistent with this finding, Franks and Lieb¹¹ reported that halothane at high concentrations has no effect on the thickness of lecithin/cholesterol bilayers. To examine further this finding and to estimate the amount of hexane in the bilayer, we have constructed absolute neutron scattering density 'strip' models for the bilayers for the different experimental conditions to ~ 10 Å resolution (Fig. 3b). Acceptable models predicted structure factors that agreed with the experimental ones to within 1%. We made several interesting observations using this approach. First, the hydrocarbon thickness of the bilayer is independent of X_H^m and apparently does not vary by more than 0.1 Å. Second, the hexane is confined largely to the centre of the bilayer in a zone ~ 10 Å thick, although at the highest X_H^m a very small amount of hexane begins to appear in the hydrophobic regions near the polar groups (Fig. 3a). Third, the scattering density of the central zone is, to within experimental error, a linear function of X_H^m . This last result means that we were performing the experiments in the Henry's law region of the bilayer's hexane solubility curve.

We have estimated the amount of D-hexane in the bilayers from the strip models. The mole fraction X_H^b of hexane in bilayer (relative to the number of acyl chains) is 0.105 for $X_H^m = 0.30$, corresponding to about 12 hexanes per 100 acyl chains. If there were no change in A_0 (the area per phospholipid at the lipid/water interface), this much hexane should have caused the hydrophobic core of the bilayer to thicken by about 1.3 Å. Our absolute neutron scattering density models, which are sensitive to changes in hydrocarbon thickness as small as 0.1 Å, show no thickening and we conclude that A_0 must increase from ~ 70 Å² to 74 Å² as X_H^m increases from 0 to 0.3. Alkanes cause large increases in the thickness of black lipid membranes^{1,7} without apparently affecting A_0 (ref. 7). We do not know why we observe no change in thickness but we note that, unlike the usual situation for black films, the activities of hexane and water were considerably less than 1 in our experiments. White²⁴ has measured the effect on bilayer thickness of variations in the mole fraction (X_D^b) of decane in the torus surrounding black films formed from glyceryl monooleate. Increasing X_D^b from 0 to 0.3 causes the thickness to increase by 1.2 Å, which suggests that water activity may be important in determining the response of A_0 to alkanes dissolved in the bilayer because the black film is formed at a water activity of almost 1.

Because we can estimate the amount of hexane in the DOL bilayers as a function of X_H^m , we can also estimate the free energy of transfer ($\mu_D^b - \mu_m^b$) of hexane from the pure liquid to the bilayer. Consistent with being in the Henry's law solubility region, we find that the ratio X_H^b/X_H^m is independent of X_H^m and is 2.86 ± 0.16 . This ratio is, of course, the activity coefficient of

the hexane in the bilayer referred to pure hexane. The hexane/hexadecane mixture is nearly ideal, so that $\mu_b^0 - \mu_m^0 = RT \ln (X_H^m/X_H^b)$, which yields 600 cal mol^{-1} . If one refers X_H^b to the number of phospholipids rather than the number of acyl chains, the free energy of transfer is 270 cal mol^{-1} , which is considerably smaller than the value of $1,560 \text{ cal mol}^{-1}$ reported by Simon *et al.*¹³ for DOL liposomes in water. Our results also differ from those of Simon *et al.*¹³ in that we estimate from their data that for $X_H^m = 0.30$, the mole fraction of hexane in the liposome bilayer is ~ 0.01 referred to the number of acyl chains; this is one-tenth the value obtained by us.

The large differences between our results and those of Simon *et al.*¹³ may exist for several reasons. First, our estimate of X_H^m may be in error because of the problems inherent in constructing absolute neutron scattering density models. A factor of 10 error

Fig. 3 *a*, 12 Å-resolution neutron scattering density profiles (relative scale) for oriented DOL multilayers containing D-hexane (D) and H-hexane (H) (temperature 22.5 °C, RH = 66% [100% H₂O, 0% D₂O], $X_H^m = 0.3$). The presence of the D-hexane is clearly revealed by the increased scattering density in the centre of the profile for the D-hexane case (D). *b*, Absolute neutron scattering density strip models whose 12 Å Fourier reconstructions agree with the syntheses in *a* with an *R*-value of <1%. The parameters of the model widths and density levels were varied to give the values shown. Similar models were constructed for the other X_H^m values, leading to the result that the central 27.4 Å hydrocarbon thickness apparently does not vary by more than 0.1 Å, assuming a constant *d*-spacing. However, as we were unable to determine the *d*-spacing with a precision of better than 0.4 Å, changes of this magnitude in the hydrocarbon thickness cannot be ruled out.

Fig. 4 Difference neutron scattering density profiles for oriented DOL multilayers containing different amounts of hexane (temperature 22.5 °C, RH = 66%). Each curve is the result of subtracting the profile of the bilayer containing H-hexane from the profile of the bilayer containing D-hexane at the same X_H^m . $X_H^m = 0.05$ (a), 0.10 (b), 0.20 (c) and 0.30 (d). These difference profiles show that the hexane is located in the centre of the bilayer and that the amount of hexane in the bilayer depends directly on X_H^m . The negative difference densities in the regions marked by the arrows are termination artefacts.

seems unlikely, however. Second, our oriented DOL multilayers exist at a water activity of 0.66 whereas the liposomes are formed in excess water. Third, the multilayered liposomes are curved whereas our oriented samples are planar. Gruen and Haydon¹⁴ have proposed that the curvature of liposomes causes a large average decrease in the solubility of alkanes in liposome bilayers. They estimate that the alkane absorption per mole of lipid in liposomes may be as small as 17% of the planar value. This is in reasonable agreement with our result taking the assumptions of their model into account.

MATTERS ARISING

Galileo's observation of Neptune

KOWAL AND DRAKE¹ have found a record in Galileo's notebooks of Neptune's position—the most precise placing being that of 28 January 1613 (Besselian date 1613.08). They note, however, a disagreement of 1 arc min between the position observed (O) by Galileo and that predicted by modern calculation (C)—using the orbit of the Jet Propulsion Laboratory, Development Ephemeris no. 102, for the C. They suggest that the effect of a yet-undiscovered exterior planet may explain this discrepancy. The 1613 residuals are listed in Table 1. To evaluate conservatively

was made during his search for Jupiter satellites, so Jupiter was in his field of view. The account and drawing for his 28 January 1613 entry both note that Jupiter, star 'a' (SAO119234), and star 'b' (the planet Neptune) were in a straight line. Kowal and Drake note that the suspect modern ephemeris correctly predicts the same lineup.

This line cuts the ecliptic at a descending angle of 25.9°. (See Table 1 or Fig. 5 of ref. 1.) Thus, if the modern orbit is approximately correct and Galileo accidentally distorted his drawing's scale, then we would expect a false latitude residual $F\Delta\beta$ corresponding to the false longitude residual $F\Delta\lambda$ according to the relation:

$$F\Delta\beta/F\Delta\lambda = \tan(-25.9^\circ) \quad (1)$$

Table 1 Residuals (O–C) for 28 January 1613

Geocentric	RA	$\Delta\alpha$	–42 arc s	Dec	$\Delta\delta$	+47 arc s
Geocentric	long	$\Delta\lambda$	–57 arc s	lat	$\Delta\beta$	+26 arc s
Heliocentric	long	Δl	–56 arc s	lat	Δb	+26 arc s

the exterior-planet hypothesis, I have computed the strength of the 1613.08 perturbation on Neptune, caused by hypothetical tenth planets in those circular orbits^{2,3} permitted by modern residuals (see Table 2). The elements and masses used were those indicated by least-squares analyses^{2,3} of Neptune longitude residuals, post-discovery as well as M. Lalande's 8 and 10 May 1795 observations (discord, –7 arc s both nights)⁴.

Table 2 shows that: the magnitude of the disturbances produced by the hypothetical exterior planets is at best in the range 10–20 arc s which, even allowing for some mass uncertainty, disagrees with the 1613 residual being nearly 1 arc min; (2) the direction is negative in all the cases listed which agrees with Table 1.

The unlikelihood of a residual as large as 1 arc min is also supported by another line of reasoning. Galileo's observation

Setting $F\Delta\lambda$ equal to the geocentric longitude residual $\Delta\lambda$ of Table 1, we substitute this into equation (1) and find that the accidental scale-distortion hypothesis predicts a false longitude residual

$$F\Delta\beta = +28 \text{ arc s} \quad (2)$$

This is within 2 arc s of the observed geocentric latitude residual $\Delta\beta$ of +26 arc s (Table 1).

Kowal and Drake note that our present uncertainty about the motion of Neptune is due to the relative shortness of the planet's continuously observed arc (less than a single full revolution since the 1846 discovery). In other words, a sizeable error in the baseline of the planet's motion may be masked by an alien perturbation. (The baseline error is $A + Bt$ in equation (1) of ref. 3. A is the error in longitude at epoch, and B is the error in the mean motion.)

However, there is no such thing as a baseline error in latitude motion (no linear expression appears in equation (2) of ref. 3, compare with equation (1) of ref. 3). Thus, if the 1613.08 latitude residuals produced by the hypothetical disturbers of refs 2, 3 are computed, it turns out that they are merely of order of magnitude 1 arc s—a far cry from the observed residual of 26 arc s.

Thus Galileo's illustration of Star SAO119234 and Neptune probably has an erroneous scale. However, if Galileo was at least correct in picturing Neptune closer to the star than modern theory predicts, then a negative 10–20 arc s longitude residual would be consistent with perturbation by an outer planet itself reasonably consistent with later longitude residuals. Hence, the slight nonlinearity of Neptune, star, and Jupiter might not be recognized.

KOWAL AND DRAKE¹ established that Galileo observed the planet Neptune and actually noted its motion. However, I must comment on their statement that "we are left, then, with the strong possibility that the ephemeris of Neptune is in error by a significant amount . . .".

It would be virtually impossible for the ephemeris of Neptune to be in error by over 26 arc s in latitude (the component of the residual perpendicular to Neptune's orbital plane) without "the existence of an unknown perturbation". As good fortune would have it, modern observations (since 1910) cover just that part of the sky in which Galileo made his observation (the exact crossing of $\alpha = 12^h$ occurred in 1943). As such, the orbital plane of Neptune, especially in that part of the sky, is established to within a small fraction of 1 arc s.

We recently attempted to incorporate Galileo's observation into the JPL Planetary Ephemeris. Even with the unrealistically high observation weight of 1 arc s, the attempt proved to be entirely unsuccessful. It was possible to adjust the longitude somewhat, but the 26 arc s latitude residual remained.

On the other hand, a perturbation of 26 arc s in latitude was easily produced using numerical experiments with an additional planet of a few Earth masses, even when the closest approach to Neptune was as distant as 10 AU. However, such perturbations usually tend

Table 2 Perturbations from hypothetical planets

Disturber's distance (AU)	Disturber's mean long		Disturber's mass ($R_\oplus/206265$)	Longitude perturbations (arc s)		
	1973.0	1981.0		1613.08	1795.35	1980.0
75	300°	304°	3.95	–8.7	–3.4	+1.1
	310°	314°	4.80	–11.4	–5.6	+1.0
	320°	324°	4.11	–9.5	–5.6	+0.6
60	310°	316°	1.55	–8.4	–1.6	+0.8
	320°	326°	2.90	–18.5	–4.9	+1.1
	330°	336°	2.61	–18.5	–6.2	+0.7
50	340°	346°	1.98	–13.8	–5.7	+0.3
	340°	348°	2.32	–4.1	–5.7	+1.1
	350°	358°	1.74	–10.9	–6.3	+0.5
	0°	8°	1.24	–12.3	–5.7	+0.1
	10°	18°	0.95	–11.6	–5.1	–0.1

to be a full order of magnitude larger in longitude than in latitude, whereas the ratio required here is only about 5:2.

To explain Galileo's residual as an ephemeris error, an unknown and rather pathological perturbation must be invoked. As Kowal and Drake state, "...it is surprising that the 'incorrect' ephemeris position still lies on the same straight line from Jupiter and the star".

One must seriously question Galileo's drawing as (1) Galileo was not interested in "extraneous objects", and (2) Galileo used a dashed line to connect stars 'a' and 'b' as he did in other cases where he wished to indicate direction only, not distance.

It is true that other pre-1900 observations of Uranus and Neptune do not seem to be consistent with those of the modern era. However, these discrepancies could be the result of observational errors, as most probably is the case here with Galileo.

KOWAL REPLIES—Although I am pleased to see these responses to our letter, I feel that an adequate assessment of Galileo's accuracy requires a much more rigorous analysis. In particular, Rawlins' assumption of a circular orbit for an 'outside' perturber is likely to be a gross oversimplification, as it would be in the case of Pluto.

Standish's reasons for questioning Galileo's drawing are not valid, for the following reasons:

Galileo clearly was interested in this "extraneous object" because he specifically noted its relative motion. Furthermore, he drew a linear scale in that diagram for the very first time. It would be quite surprising if he did not use that scale when drawing Neptune's position.

Galileo often used dashed lines, even when indicating exact distances; for example, in the drawings of SAO119234 on 25-27 January. It is certainly true, however, that Galileo's drawings are far less accurate than his measurements.

Standish's statement that the requisite perturbation in latitude was "easily produced" in his numerical experiments is suggestive. Again, Pluto shows that "pathological" cases do exist.

In any case, I hope that the question of Galileo's accuracy will not obscure the central points of our paper. These are:

We have established that Galileo observed Neptune, and noted its motion, 234 yr before Neptune was discovered.

We have demonstrated a new technique for finding other pre-discovery observations of Neptune. In particular, we should search for observations of the 1702 occultation.

Obviously, I would not insist that Galileo's drawing is accurate. If more pre-discovery observations of Neptune are found, we will be able to make a more useful assessment of the Neptune residuals. Until then, I must maintain that there is a "strong possibility" that the theory of Neptune's orbit needs to be revised; not only because of the Galileo observation, but also because of the previously known residuals.

Does spider feeding behaviour optimize dietary essential amino acid composition?

GREENSTONE¹ has concluded that the spider *Pardosa ramulosa* takes a non-random mixture of its three main prey and that this mixture optimizes the proportions of the essential amino acids in the diet. For statistical reasons, these conclusions are invalid.

The spiders fall into eight classes, which Greenstone regarded as the cells of a $2 \times 2 \times 2$ contingency table, according to whether they were serologically positive or negative for each of the three main prey. The overall proportion of triple negatives is about 25%, from which 3% must be (and was) removed to allow for moulting animals, which do not feed. If the average number of serologically potent prey in the gut is one, the remaining proportion of triple negatives is consistent with Greenstone's view that about 20% of the diet is made up of species other than the three main ones. However, some guts contain at least three prey individuals, as they are positive for all three species. Thus, there must be considerable spread around the mean, with many spiders containing no prey and some containing many.

As a result, the contingency tables may show large values of ' χ^2 ' even if the recent occurrence of one species in the diet has no effect on the relative probabilities of the spider eating another member of the same species or a member of another species.

This may be demonstrated by a simple example. Suppose we have a population comprising N_0 animals with no prey individuals in the gut, N_1 with one and N_2 with two. Further suppose that the prey are of two species, which occur in the overall proportions of p and q in the diet. Finally, suppose that these proportions are the same among the animals with one prey individual in the gut as among those with two prey individuals in the gut. Among the latter, if the presence of one species in the gut is unrelated to the presence of the other, then the propor-

tions of individuals with two individuals of the same species in the gut are p^2 and q^2 ; a proportion $2pq$ will have one prey of each species in the gut. Thus, in the population as a whole, there would be the following numbers of individuals serologically positive or negative for the two species:

$$A-, B-: a = N_0$$

$$A+, B-: b = pN_1 + p^2N_2$$

$$A-, B+: c = qN_1 + q^2N_2$$

$$A+, B+: d = 2pqN_2$$

If we treat these four classes as the cells of a 2×2 contingency table, our 'expectation' is that $ad - bc = 0$. Except for particular sets of parameter values this expectation is clearly false. In other words, the calculation of χ^2 does not provide a test of the hypothesis that the probability of consumption of each species is independent of whether or not the spider has recently consumed a member of that species.

An alternative explanation of the high proportion of triple negatives is that the proportion of the diet made up by species other than the main three is higher than 20%. If so, it scarcely seems right to ignore these other species when working out the dietary composition.

1. Greenstone, M. H. *Nature* **282**, 501-503 (1979).

GREENSTONE REPLIES—In all phases of human endeavour it is important to mind one's p's and q's; in statistics one must also ask whether they are relevant to the question at hand. Greenwood's exposition of the prey item makeup of the serologically positive stomach classes is correct and self-evident. However, only the values of a , b , c and d , and not their underlying constituents, are relevant to the test of association.

Let us consider a hypothetical human dietary example. Suppose a cafeteria serves only beans and rice and gives each diner the choice of one, two or no scoops of each. After a large sample of diners has passed through the line we tabulate the contents of their plates. If we wish to know whether the average diner is receiving a balanced diet we must add up all of the scoops of beans and rice so as to compute Greenwood's p and q , and then apply them to what we know about human nutritional requirements and the nutrient compositions of beans and rice; this is analogous to my use of the data in Tables 2 and 3 of the original paper¹ to compute the proportions of the essential amino acids in the spiders' diets.

If, however, we wish to know whether beans and rice are significantly associated in the diet, we need only concern

ourselves with the numbers of empty plates, of plates containing no rice but some (that is, at least one scoop of) beans, of plates containing no beans but some rice, and of plates containing some of each. These numbers are a , b , c and d of our contingency table, and we use the marginal totals to compute the expected numbers of each of the four kinds of plates. The numbers of scoops of beans and of rice on plates having at least some of either are no more necessary to this test of association than are the severity of cancer or the number of packs smoked per day to a test of association between smoking and lung cancer.

Plasmoid confinement by the charged particle micro-fields

DIJKHUIS¹ has recently proposed a 'boson model' which explains ball lightning in terms of electric charge. It is based on the hypothesis that turbulence in the ball lightning plasma enhances charge transfer to the point that charged vortices transport electricity the way electrons do in a superconductor. The result is described as a sponge-like structure of tenuous vortex cores nested in dense ambient plasma. By reasonings based on Landau damping and local deviations from charge neutrality it is argued that the size of the plasma vortices behaving as charged bosons apparently lies around 1 Debye length.

Plasmoid models of ball lightning are normally taken to be ruled out by the plasma virial theorem yielding the result, at least in its usual continuum formulation, that a plasmoid—defined as a self-contained bundle of electromagnetic and material energy—cannot exist. The theorem states that the plasmoid energy contents—electromagnetic as well as gas kinetic—are all positive and together drive expansion. However, the boson model for plasma turbulence is claimed to lift the virial constraint on maximum energy content with negative potential energy from interaction between plasma vortices.

The negative interaction energy necessary for the boson model conflicts with the positive-definite nature of all the energies in the fluid virial theorem. Note that the proposed boson model specifically involves interactions and structures on the plasma microfield scale that is, the Debye length. As discussed by Gerjoy and Stabler² the averaged, 'smoothed-out', plasma descriptor inherent in the fluid virial theorem may, in some respects, be misleading. Resort has then to be taken in

a perfectly general and purely particle system formulation of the virial theorem. The electrostatic energy is then given by the double sum

$$W_{el} = \frac{1}{4\pi\epsilon_0} \sum_{i < k} e_i e_k r_{ik}^{-1}; r_{ik} = |\mathbf{r}_i - \mathbf{r}_k| \quad (1)$$

Note that a slight excess of negative charges around each positive charge will make W_{el} go negative². However, this is also that condition which will distribute the source charges e_k so as to minimize the electrostatic potential ϕ^i at the field point i as well as to make the related field strength $\mathbf{E}^i = -\nabla\phi^i$ small

$$\phi^i = \frac{1}{4\pi\epsilon_0} \sum_{k \neq i} e_k r_{ik}^{-1} \quad (2)$$

The influence of a negative contribution W_{el} , as indicated above, to a virial theorem reasoning has been discussed and estimated in ref. 2. For a plasma with thermal energy like that assumed for the boson model it has been proved to be insignificant, thus validating the results of simpler fluid virial theorem reasoning.

In a similar way, the magnetic energy W_m and vector potential $\mathbf{A}^i$ can be expressed in terms of the microscopic currents $\mathbf{j}_i$ and $\mathbf{j}_k$ carried by the charges e_i and e_k

$$W_m = \frac{\mu_0}{4\pi} \sum_{i < k} \mathbf{j}_i \cdot \mathbf{j}_k r_{ik}^{-1}, \mathbf{A}^i = \frac{\mu_0}{4\pi} \sum_{k \neq i} \mathbf{j}_k r_{ik}^{-1} \quad (3)$$

Here it is noted that a hypothetical current distribution where adjacent current elements are directed oppositely would make W_m go negative but, also, make $\mathbf{A}^i$ and $\mathbf{B}^i = \text{curl } \mathbf{A}^i$ attain vanishingly small values. Contrary to the claim in ref. 1, there seems to be no way by which the magnetic interaction energy can attain a large enough negative value to affect significantly the expansion-driving thermal effects. Essentially the same result, in conflict with the proposed boson model for ball lightning, was also obtained by Liboff and Lie³ who used instead the quasi-relativistic Coulomb gauge expression for $\mathbf{A}^i$ in their derivation of a general virial theorem in a particle formulation.

I conclude that the various formulations of the virial theorem as discussed above are all based on usual charged-particle electrodynamics where fields and forces follow from positions and velocities. The power then of the theorem to deny plasmoid self-confinement lends support to that theory⁴ where the confinement is provided by the radiation fields associated with particle acceleration.

E. A. WITALIS

Research Institute of National Defense,
Stockholm, Sweden

DIJKHUIS REPLIES—It is a delusion to claim perfect generality for the purely particle system formulation of the virial theorem. Particles in a plasma obey classical equations of motion as long as electromagnetic fields do not change appreciably over their dimension. This classical limit is certainly appropriate for any stable plasma in a smooth electromagnetic field. However, in a turbulent plasma electromagnetic fields may have strong local fluctuations. In our approach to ball lightning, turbulent fluctuations of local electromagnetic fields become so violent that the motion of particles must be treated quantum mechanically.

A particle with mass m and charge q , moving with velocity $\mathbf{v}$ in an electromagnetic field with vector potential $\mathbf{A}$ and electrostatic potential ϕ , has canonical momentum $\mathbf{p} = m\mathbf{v} + q\mathbf{A}$ and hamiltonian $H = (\mathbf{p} - q\mathbf{A})^2/2m + q\phi$. In our quantum-mechanical context, $p = -i\hbar\nabla$ is an operator which does not commute with arbitrary functions of position vector $\mathbf{r}$. Thus $\frac{1}{2}q(\mathbf{v} \times \mathbf{B} - \mathbf{B} \times \mathbf{v})$ (ref. 1) denotes the Lorentz force on a wave packet moving in a magnetic field $\mathbf{B} = \nabla \times \mathbf{A}$. In the absence of magnetic fields a wave packet has $\mathbf{p} = m\mathbf{v}$, $H = \frac{1}{2}m\mathbf{v}^2 + q\phi$, and the virial theorem reads $d/dt \langle \mathbf{r} \cdot m\mathbf{v} \rangle = m\langle \mathbf{v}^2 \rangle - q\langle \mathbf{r} \cdot \nabla \phi \rangle$ (ref. 1), where the brackets denote expectation values with wave functions from the energy representation. Inclusion of magnetic interaction between wave packets leads after lengthy commutator bracket calculations to a quantum-mechanical virial theorem of the form

$$\frac{d}{dt} \langle \mathbf{r} \cdot m\mathbf{v} \rangle = m\langle \mathbf{v}^2 \rangle + \frac{1}{2}q\langle \mathbf{r} \times \mathbf{v} \cdot \mathbf{B} + \mathbf{B} \cdot \mathbf{r} \times \mathbf{v} \rangle - q\langle \mathbf{r} \cdot \nabla \phi \rangle \quad (1)$$

where for a stable plasmoid at least one term on the right has to be negative. With $\rho^{1/2}e^{i\theta}$ as wave function for a boson state with charge density ρ and phase θ (ref. 2), expectation values in equation (1) include the quantum-mechanical term $-\hbar^2/2m(\nabla^2\rho^{1/2})/\rho^{1/2}$, from which a spherically symmetric solution with negative energy was derived in our letter³. In the classical limit $\hbar \rightarrow 0$, expectation values can be dropped and all quantities commute, so that the usual terms for kinetic, magnetic and electric energy are recovered.

I maintain that (1) the quantum-mechanical version of the virial theorem admits electromagnetic self-confinement of a plasma, and (2) strong plasma turbulence leads to a self-confined boson state in ball lightning.

BOOK REVIEWS

Science and faith in mind

Stuart Sutherland

Brains, Machines and Persons. By Donald MacKay. Pp.114. (Collins/W. Eerdmans: 1980.) Pbk £3.50, \$4.95.

BOTH as a brain scientist and as a Protestant, Professor Donald MacKay is an honest man. *Brains, Machines and Persons* gives a brief but stimulating and lucid account of the human brain and of models of its workings cast in the form of computer programs. This account is a preamble to an attempt to reconcile the scientific and the religious view of human beings. He makes a better shot at it than others, such as Sir John Eccles, who have confronted the same dilemma. Professor MacKay rightly eschews both the argument for free will based on the Heisenberg uncertainty principle and any form of interactionism between mind and body, though he does not set out the reasons why these proposals are unsatisfactory. (The first can only account for random behaviour whereas the outcome of deliberate choice is far from random; the second implies that the brain is not a physical system in the ordinary sense of the word since at some point it is being influenced by non-physical events.)

MacKay's own solution to the mind-body problem is that human beings can be viewed in two ways, from the inside as a series of mental processes (the I-story) and from the outside as a series of physical events. He does not deny that the workings of the brain and nervous system may be deterministic and, at least in principle, predictable. He resolves the problem of freedom of the will by arguing that if someone predicts from a knowledge of his own brain state that he will do something, his brain is itself changed by this knowledge: this change may lead to the prediction being falsified since the brain cannot take into account the effects of the change in its own state in order to predict its future behaviour without falling into an infinite regress. MacKay then raises the question "suppose a super-scientist... produced a specification of [your brain's] immediate future... Would you be correct to believe it?". He argues that you would not, since when the super-scientist gave you his prediction, your brain state would change and hence his prediction might fail. This is an argument with which I have dealt elsewhere ("Is the Brain a Physical System" in *Explanations in the Behavioral Sciences* edited by R. Borger and F. Cioffi, Cambridge University Press; 1970). The problem is that the super-scientist might have taken into his own calculations the effects of telling you what

you will do, and have delivered the prediction only after making sure that you will still do what he predicts even after being informed that you will do it. MacKay is right in thinking that if the brain scientist delivers *all* the thought processes that underlie his prediction, then your brain state may be changed and the prediction may fail: once again an infinite regress arises. But MacKay fails to note that you may have other good reasons for believing the super-scientist, for example, you may know that he always gets his predictions right.

Despite this flaw in MacKay's argument, there is something to be said for the theses that mental events and physical states of the brain are one and the same thing viewed in different ways and that we can only choose freely because we cannot ourselves predict what we will do. He argues that it is the latter aspect of people that makes each a morally responsible agent. Even if this were true, it leaves open the question of how we view others. If they can legitimately be viewed as complex physical systems, does it make sense to praise and blame them? To the extent that we know the cause of an action, we tend not to attribute praise or blame. Someone who becomes extremely bad-tempered because of a tumour in the hypothalamus does not deserve censure. Here MacKay draws a distinction between brain hardware and brain

software. If the hardware has gone wrong, no moral responsibility is attached. If it is the program being executed in the brain that is at fault, then it is proper to attach blame. Ingenious though this argument is, it again seems fallacious: suppose we knew enough about someone to predict from his genetic make-up and his environmental history exactly what programs were running in his brain, would that not make us want to excuse him for evil acts?

MacKay makes further play with the distinction between the brain's hardware and software. He even suggests that one solution to the problem of resurrection would be to incorporate the program that runs in each individual's brain in some medium other than the human body. He faces the fact that in the distant future we may be able to build computers as intelligent as ourselves and having many, if not all, of the attributes that we value in ourselves (other than being born of man). He believes that the existence of such machines would not lower the status of human beings, though it would raise that of computers. I once asked him whether such a computer would be a candidate for entry into the kingdom of heaven: with his usual honesty he replied, after careful reflection, that he could see no reason why not. □

Activity in the blood-brain barrier

Michael Bradbury

The Cerebral Microvasculature: Investigation of the Blood-Brain Barrier. Edited by Howard M. Eisenberg and Robert L. Suddith. Pp.342. (Plenum: 1980.) £24.89, \$39.50.

AFTER the idea of a blood-brain barrier arose at the turn of the century, there was prolonged controversy as to whether it was sited at the level of the capillary endothelium or at that of the sheath of glial end-feet. In 1946, Krogh showed great foresight in not only placing the barrier at the capillary level, but in considering it to have the typical properties of a cell membrane and perhaps to be capable of secretion, i.e. active transport. Physiological and ultrastructural studies in the whole animal have fully confirmed this interpretation, and it is now accepted that

the cerebral endothelium functions like a tight epithelium and is capable of active transport.

The Cerebral Microvasculature contains the edited manuscripts from a symposium held at Galveston, Texas, in 1979. The first section deals with transport properties and permeability. It largely contains reports of the properties of isolated whole capillaries of cultured endothelial cells and of parts of capillaries, plasma and basement membranes for example. Among a number of interesting papers, the uptake of various solutes into isolated capillaries as a model for transport across the barrier *in vivo* is reviewed by Betz and Goldstein, and the biochemical properties of isolated capillaries are considered by Mršulja and Djuričić. Eisenberg and his colleagues discuss the demonstration of an ouabain-

sensitive potassium pump at the abluminal membrane of the endothelial cells and relate this to a high concentration of the Na-K-ATPase in these cells compared with that in both non-cerebral endothelial cells and in cerebral cortex as a whole. Brendel and Meezan look critically at the technique for isolating cerebral capillaries and compare the composition of the basement membrane from brain vessels with that from retinal vessels and renal glomeruli.

One is more convinced of the potential of isolated capillaries and cultured endothelial cells as a means of studying control of transport at the blood-brain barrier than as a model for transport across it. Thus, DeBault and Cancilla report intriguing experiments in which the co-culture of endothelial cells with glioma cells leads to a maintenance of a high content of γ -glutamyl transpeptidase in the former. This enzyme is highly specific to cerebral capillaries and the results strengthen the concept that the glial end-feet induce the very particular properties of these vessels. In the same context, Anders and colleagues describe curious "assemblies" of intramembranous particles which occupy the cytoplasmic face of astrocytic plasma membranes. They are particularly numerous in the perivascular membranes of the glial end-feet and could be part of a mechanism for influencing the capillaries.

Isolated capillaries contain adenylyl cyclase (as discussed by Palmer and colleagues) and this enzyme is activated by noradrenalin (mainly β_2 effect), dopamine and in the rabbit by histamine. This possible link in a control of permeability is of particular interest, since cerebral capillaries are contacted by noradrenergic nerve terminals probably originating from cell bodies in the locus coeruleus. The evidence that these control permeability to labelled water independently of any effect on cerebral blood-flow is considered by Hartman and colleagues.

The second section of the book is concerned with perturbation of the barrier and lacks, for me at least, the excitement of the first section. It contains good articles by Nemoto on transport during anaesthesia, by Rapoport on measurement by his new technique of permeability in relation to lipid solubility and of permeability after osmotic shock, and a definitive short review of the blood-brain barrier in acute and chronic hypertension by Johansson.

This book is much better than the usual collection of manuscripts from a symposium. It should be of interest to all those concerned with the blood-brain barrier or with transport across the capillary wall in general. Most particularly, it is valuable as a fairly comprehensive survey of the present state of the art with regard to isolated cerebral capillaries and endothelial cells. □

Michael Bradbury is Professor of Physiology at King's College, University of London, and author of *The Concept of the Blood-Brain Barrier* (Wiley, 1979).

American Ice Age mammals

R.J.G. Savage

Pleistocene Mammals of North America. By Björn Kurtén and Elaine Anderson. Pp.442. (Columbia University Press: 1980.) \$42.50, £21.20.

BJÖRN Kurtén's *Pleistocene Mammals of Europe* (Weidenfeld & Nicolson, 1968) has become a classic; it broke new ground and remains a frequently quoted text. Now the author, in collaboration with Elaine Anderson, presents the *Pleistocene Mammals of North America*. The format of the new book is similar, but more detailed treatment is given to major sites and their faunas are compared with those of adjacent continents, a useful feature lacking in the earlier work. Although entitled "Pleistocene" mammals, the authors wisely extend their coverage back to include the whole of the Blancan, to a base of around 3.5 million years. Their geographical limits are Canada, the USA and northern Mexico.

In Part I some 250 faunal sites are listed, with notes on geology, geography, ecology and faunal composition. The listing is alphabetical for each state, and the faunas are grouped as Blancan, Irvingtonian and Rancholabrean. There follows a discussion of intercontinental correlation and migrations between North and South America and between North America and Eurasia.

In the second part of the book critical and annotated lists are given for all Blancan and Pleistocene mammal species on the continent. The taxonomic treatment is detailed, giving information on synonymy, geographical and stratigraphical distribution, anatomical characteristics, relationships, evolution, migration and extinction of each species. Some 562 species are treated; extant species are included only where they have a fossil record. The diagnostic features detailed for each species of necessity use highly specialized terms, which however are not explained; e.g. on p.285 a horse species is characterized by having "ectoflexid of lower molars penetrating deeply into the metaconid-metastylid isthmus". In this second section the material ancillary to the text leaves something to be desired. The illustrations depict only a few sample species and the dental characters are not annotated. The quality of the drawings is highly variable; most are taken from the literature without alteration, thus the orientations and scales are often inconsistent and the techniques of drawing differ widely. Further, they are poorly arranged so that there is much wasted space. The maps showing species distribution are clear, though not numerous, and the addition of some reconstructions adds interest, especially for the non-specialist. The tables are important; in Appendix 2 the stratigraphical range of every species is tabulated.

The book is a formidable and scholarly compendium of information: thorough, accurate and up to date. It will be an invaluable reference source for those working not only on Pleistocene faunas, but on problems of evolution, extinction and biogeography. The authors are indeed to be congratulated on so ably treating a colossal mass of data in a digestible and attractive form. □

R.J.G. Savage is Reader in Vertebrate Palaeontology at the University of Bristol.

Stone Age summary

Derek Roe

Early Man in Britain and Ireland: An Introduction to Palaeolithic and Mesolithic Cultures. By Alex Morrison. Pp.209. (Croom Helm/St Martin's Press: 1980.) Hbk £12.95, \$35; pbk £7.95.

THE Mesolithic period in Britain lasts for around 5,000 years, the Palaeolithic for perhaps 500,000. Books on British archaeology seem to be produced in an inverse relationship to the durations of the successive periods. Lavishly illustrated information on Saxons, Vikings, Romans or Iron Age groups beckons from every shelf, but the choice is limited for those trying to study Early Man in Britain. Clearly, Alex Morrison's book meets a real need and let us hope the reading public will think so as well as teachers and students of archaeology, because early Prehistory in Britain, however unspectacular by comparison with, say, its equivalent in East Africa, has considerable fascination and importance in an Old World context.

That, however, does not make it an easy subject for a book. Sites exist in thousands, but the material from them is widely scattered; dating, for the Palaeolithic, is extremely difficult, and relatively few fully documented modern excavations have taken place. Undisturbed sites are rare: usually all fragile objects and much of the environmental evidence has gone. The British Mesolithic is a little better off in these respects, but even here the situation is far from ideal. For broad interpretation, one needs to know much about the Palaeolithic and Mesolithic of continental Europe: the geographical situation of Britain positively demands this, as Mr Morrison rightly stresses.

In these circumstances, one can either set out to write a massive book on the Palaeolithic and another on the Mesolithic, each based on exhaustive first-hand study of the extant material, or one can produce an outline summary, based almost entirely on the literature. Alex Morrison has opted

for the latter, and makes no extravagant claims for the result. Specialist colleagues will doubtless complain of brevity, unevenness, generalizations and omissions, but such specialists are relatively few and instead of complaining they should write the definitive texts whose absence they deplore.

In his two opening chapters, the author covers essential introductory subjects, including Pleistocene geology and environments, long-range dating methods, hominid evolution and so forth. Palaeolithic archaeology is very different from other kinds and preliminary discussion of these topics is certainly needed. The rest of the book mainly follows the archaeological sequence from Early Acheulian and Clactonian to the end of the Mesolithic, with an intermission to discuss the environmental changes that mark the start of the "postglacial" period, as we call it somewhat naively, since it's really only another interglacial. The approach depends heavily on individual British sites throughout, and the Mesolithic is studied regionally. Plenty of references are given, which serious students will need to follow up to supplement the brief descriptions provided. Some major relevant sites in Europe, and occasionally further afield, are mentioned in passing, though there is no serious attempt to set the British sequence firmly in its context stage by stage.

Plenty of major questions arise as soon as one starts to study the British material. For example, how does the British local Pleistocene sequence correlate with various fuller and better documented ones in Continental Europe? How do the named stages in Britain match the numbered "isotope stages" of the deep-sea core record? There are clearly gaps in the British succession, but just where do they come? Are we at present failing to observe a whole glacial-interglacial cycle, or even more, somewhere in the British Middle Pleistocene, thereby misleadingly con-

tracting our geological and archaeological sequences? How early is our "Early Acheulian" by world standards? What role does the Clactonian play? Why is the British Middle Palaeolithic so sparse, when the French Mousterian is so rich and varied? Has our Upper Palaeolithic anything at all to do with the classic sequence in southwest France, or can the whole of it be explained better by reference to central and northwest Europe? How much of our Mesolithic is attributable to direct connections with the Continent across a North Sea land-bridge, and how much represents indigenous development within Britain, showing variability related to the exploitation of differing environments and local resources? These are a few of the crucial and fascinating problems still to be solved: the reader will find awareness of most of them in the book, but might have liked more guidance for his thinking about possible solutions.

One never knows, these days, whether illustrations reflect an author's approach or a publisher's budget. Here, they are of rather mixed quality and usefulness. The line drawings are clear, but many of the photographs contrive to conceal as much information as they provide. All the photographs are of artefacts, chosen entirely from local sources in Glasgow, where the author is a lecturer in archaeology at the university: in a few cases are they the best examples available in Britain to document the point in question and some are even unprovenanced finds. The drawings include several maps, but hardly any plans or drawn sections of sites. The text of the book, which contains much that is up to date, deserved more generous and varied illustration, but perhaps one kind of expansion would have led to another and it would have ceased to be an outline account at all. □

Derek Roe is University Lecturer in Prehistoric Archaeology and Director of the Donald Baden-Powell Quaternary Research Centre at Oxford.

Polymer trio

Herbert Morawetz

Polymers, in 3 parts. *Methods of Experimental Physics*, Vol.16. Edited by R.A. Fava. Part A pp.590; Part B pp.421; Part C pp.528. (Academic: 1980.) \$55, £30.80; \$45, £25.20; \$59, £33.20.

THE publication of an encyclopaedic treatise with the scope of these three volumes is a major event for polymer physicists. As with all monographs in which chapters are written by experts, the success of the enterprise depends to a large degree on the manner in which the editor has defined the intended readership, selected the areas of greatest interest and chosen the authors who could best survey these areas. The first criterion does not appear to have been always considered; thus, while most of the chapters demand of the reader a high degree of scientific sophistication, several are written at a much lower level. Further, some contributors discuss almost exclusively experimental techniques, while others include valuable examples of experimental results. Most of the authors were well chosen and some may be regarded as leading authorities in their field. As for the choice of subject matter, it would seem to me that some contributions — "Inelastic Electron Tunneling Spectroscopy" and "Positron Annihilation", for example — are of rather marginal interest to the polymer physicist, while the absence of chapters on dynamic light scattering and on ESCA is to be regretted.

The first of the three volumes covers molecular structure and dynamics. For me, the highlight is the superb chapter on high-resolution NMR spectroscopy. It covers the numerous applications very well and includes broad-line NMR studies. My only regret is the absence of reference to the polymer association studies of Schneider and Spevacek and a mention of NMR studies of helix-coil transitions in polypeptides. Other outstanding chapters are those on infrared and Raman spectra, Rayleigh-Brillouin scattering in polymers and small-angle light scattering.

It is unfortunate that this valuable volume is prefaced by a rambling introductory chapter which falls far short of what is required. The chapter on molecular weights is extremely poor and contains many glaring errors. It is also a pity that the volume contains no mention of viscoelasticity, dielectric dispersion and ultrasonics (discussed in Part C for polymers in bulk) which have important applications to polymer solution studies.

Part B is subtitled "Crystal Structure and Morphology". Here, my major criticism is that several subjects of considerable interest are missing. There is no mention of the macroscopic crystals which can be obtained from diacetylene derivatives in a process in which the

By Alan Sorrell, from *Early Man in Britain and Ireland*.

Reconstruction of activities at Starr Carr, Vale of Pickering, Yorkshire, c. 7,500 BC.

polymer grows homogeneously in the monomer crystal. Epitactic polymerization is another phenomenon which might have been mentioned, and I feel that electron diffraction should have been treated more fully.

In Part C ("Physical Properties") the authors have apparently assumed that they were to write about polymers in bulk. This is an unfortunate limitation in an otherwise excellent volume, since a number of the techniques yield valuable data when applied to dilute polymer solutions. Plazek's excellent chapter on viscoelastic and steady-state rheological response would have benefited from the inclusion of experimental data; it is most surprising that the dependence of polymer viscosity on chain length and temperature is not mentioned. Also, Rutherford and Brown might have discussed the effect of the rate

of loading on stress-strain measurements and Hay's treatment of polymer orientation could have included a mention of anisotropic polymer solutions. The chapter on polymer alloys stresses excessively cohesive energy density, which is known to be inadequate in predicting polymer compatibility. As for the chapters on the electrical behaviour of polymers, I wish that polymer conductivity had received a fuller treatment and that the important phenomenon of piezoelectricity had been at least mentioned.

However, the various criticisms detailed above should in no way detract from the value of this survey. The books should be part of the library of every serious polymer scientist. □

Herbert Morawetz is Director of the Polymer Research Institute at the Polytechnic Institute of New York.

The philosophy of geochemistry

Arthur W. Rose

Environmental Geochemistry: A Holistic Approach. Ecological Studies, Vol. 35. By John A.C. Fortescue. Pp. 347. (Springer-Verlag: 1980.) DM 69, \$40.80.

ALTHOUGH this book is entitled *Environmental Geochemistry*, its main emphasis is on landscape geochemistry and related aspects of geochemistry in the surficial zone of the Earth. Landscape geochemistry deals with the chemical interactions between rocks, the atmosphere, natural waters and living organisms, and thus furnishes the geochemical background for many environmental problems. Most previous discussion of the subject has been by Russians, notably A.I. Perel'man. A major contribution of this book is to summarize the Russian approach and results, which are referred to throughout the text.

The opening chapters describe landscape geochemistry in broad outline and also the purpose of the book, which is to introduce a general approach and mode of thinking for conducting environmental geochemical studies and for comparing results from different areas; the history and concepts of landscape geochemistry are summarized (geochemical cycles, landscape prisms, landscape types, mobility of elements), together with the permutations and complications created by space, time, chemical complexity and varying scientific effort.

Each of the important concepts and principles of landscape geochemistry is then discussed in detail. These include element abundance in rocks, waters, plants, animals and air, and the speciation of these elements into abundances of different form (exchangeable, acid extractable and so on); element migration

or relative mobility of elements under varying conditions; geochemical flows by various types of surface and near-surface transport; geochemical gradients such as decrease of chemical content away from an orebody or pollution source, and climatically controlled gradients; geochemical barriers formed by changes in chemical environment along a flow path, resulting in precipitation and accumulation of selected elements; historical geochemistry, leading to recognition of changes in chemistry with time; and geochemical classification of landscapes. These chapters include many tables giving basic geochemical data and numerous examples and figures from environmental and exploration geochemical studies.

The book concludes with an interesting chapter on practical applications of landscape geochemistry which illustrates uses in geochemical exploration for minerals, environmental pollution, waste disposal, plant and animal nutrition, and geoepidemiology. An integrated view of all elements in a landscape prism and of changes with time and space is stressed throughout.

The author has a philosophical and pedagogical approach to his subject, and repeatedly emphasizes the organization of ideas and information rather than the information itself. Most experienced environmental and exploration geochemists are probably familiar with many or all of the concepts discussed, but the book draws from a diverse background, and all those investigating chemical processes on the Earth's surface will probably gain new ideas from the book. □

Arthur W. Rose is Professor of Geochemistry at The Pennsylvania State University and is co-author of Geochemistry in Mineral Exploration (Academic Press, 1979).

Taxonomy is far from boring

Otto Kandler

Microbiological Classification and Identification. The Society for Applied Bacteriology Symposium Series, No 8. Edited by M. Goodfellow and R. G. Board. Pp. 408. (Academic: 1980.) £20, \$46.

CLASSIFICATION and identification is often considered to be a boring, old-fashioned subject dealing with the simple morphological and physiological properties of organisms. This volume, however, demonstrates the opposite. The 15 papers, presented by leading experts at the 1978 SAB symposium at Birmingham, describe the highly sophisticated applications of the most advanced biochemical and molecular biological principles and techniques for exploring and determining new taxonomical characters. They do not, however, give detailed prescriptions on how to carry out the identification of a particular organism, nor do they contain phylogenetic trees or keys for the classification of particular taxa or groups of bacteria. Since none of the contributions cover viruses or fungi, the reader may feel somewhat misled by the term "microbiological" used in the title.

One paper deals with the principles of computer-aided numerical taxonomy in a way quite understandable to the non-mathematician. Others are concerned with the application of DNA-DNA hybridization and with the role of neutral mutations, insertion sequence elements and plasmids in the genotypic variability of bacteria. Aspects of fine-structure research and cell wall and lipid chemistry are also dealt with. In addition, papers are devoted to the applicability of enzyme and protein patterns of various kinds and to the chemical analysis of fermentation products. The suitability of serological methods is discussed with respect to their use in detecting food-poisoning toxins, the ability of phage-typing with respect to the classification of plant-pathogenic bacteria, and the usefulness of determining enzyme activities is exemplified by the identification of clinical specimens.

Apart from the omission of viruses and fungi, there are other gaps — I looked in vain for a concise contribution on the implications of sequence analysis of proteins and nucleic acids for the classification of taxa above the species level. Altogether, though, this volume will be most informative for advanced students and research workers in bacterial taxonomy; it will, however, not cover the everyday needs of the clinical or food bacteriologist. □

RES PONDENCE

Continued from page 82

Nature Conservation Council has publicly stated that such sites are "gems" (BBC Radio 4, 22 January). He is indeed correct, for, like jewels, they provide neither nourishment nor habitation nor protection (the three necessities of life). But they are worse than jewels for they cannot be traded in time of hardship and instead of representing riches they are a permanent impoverishment to their owners. The usual epithet for such items is "white elephants".

Let us have no more of this folly in the name of science. The value to science of objects or phenomena lies not in themselves but in the information they yield to study. Once this information is recorded and published whatever value remains in the objects or phenomena is of no value to science, for unless the original study was incompetently executed nothing new will be learned by preservation. I do not in the least condone the wilful pursuit of rare organisms, or the careless or selfish pollution of the environment, and I admit the possible future benefits which may be derived by maintaining "gene banks" of rare forms of cultivated organisms, but all that is quite a different matter. Should there be a popular demand for the preservation of areas of wilderness then justice requires that the populace provide compensation to the owners, but let there be no mistaken idea that this cost, which will be measured in hundreds of thousands of pounds annually, is a deserving use of the funds made available to science, nor that compulsion is justified by the supposed advance of knowledge. If any individual or body of scientists presumes that it is only necessary to legislate or to spend enough money in order to halt not only natural selection but also the very evolution of the inanimate world, such presumption is an affront to reason and must bear the condemnation of responsible scientists for misleading those who know no better.

Origin of cancer

SIR — Cairns's¹ article is a welcome breath of fresh air in trying to put the causes of cancer into a realistic perspective. However, he could have strengthened his case for genetic transposition as a major cause by considering the relevance of DNA double-strand breaks as a molecular mechanism. Over the last few years Leenhouts and Chadwick² have convincingly demonstrated that the biochemical basis of malignancy lies most probably in the generation of double-strand breaks—lesions which cannot be repaired but which may result in genetic transposition. The evidence comes from many sources including those quoted by Cairns as well as radiation damage effects and cell-fusion experiments. Since double-strand breaks are necessary for some mutations, chromosomal abnormalities and genetic transpositions, Occam's razor

would suggest this as a suitable model on which to test Cairns's hypothesis.

2. Leenhouts, M.P. & Chadwick, K.M. *Int. J. Radiat. Biol.* **33**, 357-370 (1978).

SIR — John Cairns's speculative article¹ on the origin of human cancer is open to criticism both for what it says and for what it leaves unsaid.

Garner and Hertzog² have already drawn attention to the tenuous nature of the evidence on which Cairns bases his suggestion that "Chemical mutagens (of the kind detected in the usual tests for mutagenicity) seem unlikely to be rate-limiting components in most human carcinogenesis" and that "large-scale changes in the genome (such as rearrangements and deletions) seem to be more hazardous than the local changes produced by conventional mutagens". They might have put their case even more strongly.

First, the fact that patients with xeroderma pigmentosum (XP) do not show a high incidence of cancer in tissues other than skin may imply only that cancer in these other tissues is not associated with the formation of "UV-like" lesions³ because the essential anomaly in XP seems to be failure to recognize lesions of this kind rather than inability to excise and repair DNA lesions in general.

Second, the association of chromosomal abnormalities with a high incidence of leukaemias, lymphomas and carcinomas in patients with Bloom's syndrome tells us nothing about the aetiology of cancer in the vast majority of the population who do not have Bloom's syndrome. Similarly it seems unjustifiable to assume that most cancer cells have an abnormal karyotype simply because this is often the case with cells from leukaemias, lymphomas, meningiomas and gliomas. Moreover, even if this generalization were true, it is conceivable, as Cairns himself points out, that the observed chromosomal rearrangements could have resulted from "trivial secondary events that occur after all the rate-limiting steps of carcinogenesis have been completed".

Third, it is not clear how the phenomenon of carcinogenesis in experimental animals by implanted films of plastic (and other materials) supports Cairns's argument. The underlying mechanism is still far from clear but, contrary to what Cairns suggests, Karp *et al.*⁴ (whose work he cites) concluded that the hypothesis that tumours develop because the cells have lost the restraining influence provided by contact with each other, was specifically excluded by their observations. It is also worth pointing out that this form of carcinogenesis does not seem to have been reported in man despite the fact that foreign material of various kinds, and sometimes in sheet form, has been used in human surgery for many years (for example, in hernia repair, orthopaedic surgery and vascular surgery).

Finally, even if large-scale changes in the genome were shown to occur in cells from most common human cancers, this would not

exclude the possibility that environmental pollution by chemical mutagens of various kinds, including mutagens detectable by the Ames test, plays an important part in the aetiology of human cancer. Many such mutagens, as Garner and Hertzog point out, and as Cairns admits, can increase the frequency of sister chromatid exchange and cause other chromosomal interactions in mammalian cells. The extent to which such changes are "functionally equivalent to genetic transpositions" seems to be of secondary importance in comparison with the question of whether or not they are associated with a high incidence of cancer.

As regards what is left unsaid, Cairns seems to equate "the creation of a cancer cell" with the development of cancer. Thus, while he recognizes the possible role of DNA repair mechanisms in preventing the emergence of cancer cells, he ignores the possibility, which I have discussed at length elsewhere⁵, that homeostatic mechanisms of another kind may operate to destroy transformed cells or prevent them from dividing, and thus prevent the development of overt cancer. It is clear from the work of Mondale and Heidelberger⁶, and others, which Cairns cites, that there may be a long interval between the application of a mutagen to cells in tissue culture and the emergence on repeated subculture of cells with the hallmarks of malignant transformation. The mechanisms responsible have not been fully elucidated but there seems no reason to doubt that they also operate *in vivo* and play a part in delaying the development of tumours in response to exposure to chemical and physical carcinogens; this, however, does not exclude the possibility that, *in vivo*, other mechanisms are also involved.

The long interval, often of many years' duration, which can occur between the locally successful removal of a primary tumour and the appearance of metastases would seem to imply either that cancer cells can remain dormant, or that cell proliferation may be balanced by cell death, for a long time, and studies of tumour cell population kinetics in both animals and man confirm this conclusion⁵. It has, moreover, been observed that the period of apparent dormancy may be abruptly terminated by experimental⁷ or therapeutic⁸ procedures. If metastatic tumours can be held in check in this way, why not primary tumours? My colleagues and I have recently described a technique which makes it possible to investigate this question directly in an animal model^{9,10}.

Awards

Dr Alvin M. Weinberg (Oak Ridge) and **Sir Rudolf E. Peierls** (Oxford) have been selected to receive the US Department of Energy's Enrico Fermi Award for 1980.

Dr Seymour A. Papert (Massachusetts Institute of Technology) has been awarded the Seventh Marconi International Fellowship for his work in computer education.

The William Bate Hardy Prize of the Cambridge Philosophical Society has been awarded to **Dr C. Milstein** (Fitzwilliam College) for his distinguished work on monoclonal antibody techniques.

The Zoological Society of London has made the following awards for contributions to zoology in 1980: The Scientific Medal to **Dr J. M. Elliot** (Freshwater Biological Association, Ambleside); The Stamford Raffles Award to **Dr A. J. Woakes** (University of Birmingham); The Zoological Society of London Frink Medal for British Zoologists to **Professor W. H. Thorpe** (University of Cambridge); The Prince Philip Prize to **James Burton** (of King's College, Taunton).

The André Lichtwitz Prize (10,000 French Francs) is awarded every year by INSERM for distinguished clinical or fundamental research on calcium and phosphorus metabolism carried out by a French or foreign scientist (or a team). Applicants who have previously applied are allowed to apply again. Details from: Director of INSERM (c/o Mlle C. CHIROL, 101 rue de Tolbiac 75645 Paris Cedex 13, France).

Appointments

Arthur L. Schawlow (Stanford University) has been appointed President of The American Physical Society.

Professor Graham Milbourn has been appointed Director of the National Institute of Agricultural Botany at Cambridge.

Gordon Bell who has been Director of the Royal Observatory, Hong Kong for the past 15 years retired in January, to be succeeded by **Mr J. E. Peacock**. Mr Bell has been appointed to the newly created post of Science Adviser to the Hong Kong Government.

Dr George Stewart, has been appointed to the Chair of Petroleum Engineering at Heriot-Watt University, Edinburgh, in succession to **Professor James Brown**, who retires on 31 March 1981.

The University of Newcastle upon Tyne has made the following appointments: **Dr F. K. Kong** to the Chair of Structural Engineering from 1 September 1981, and **Dr C. J. Hull** to the Chair of Anaesthesia from 1 January 1981 and to the Headship of the Department of Anaesthesia from 1 January 1981 to 30 September 1986.

Dr Anthony G. Atkins has been appointed Professor of Mechanical Engineering at Reading University from 1 March 1981.

Meetings

5-8 October, **Hormones and Cell Regulation**, Bischoffsheim (Dr G. Schultz, Pharmakologisches Institut der Universität Heidelberg, im Neuenheimer Feld 366, D-6900, Heidelberg, Germany).

5 October — 6 November, **Land Use Planning and Environment Applications**, Flagstaff (J. A. Reinemeund, US Geological Survey, National Center — M/S 917, 12201 Sunrise Valley Drive, Reston, Virginia 22092, USA).

6-9 October, **Safety in Communications and Transport**, Genoa (IIC, Via Pertinace, Villa Piaggio, 16125 Genoa, Italy).

5-10 October, **Tropical Ecology and Resources Management**, Shopal (Prof. K. C. Misra, Secretary ISTE, Dept of Botany, Banaras Hindu University, Varanasi-221005, India).

6-10 October, **Microprocessors in Control of Mechanical Function**, Leeds (The Institution of Mechanical Engineers, 1 Birdcage Walk, London SW1, UK).

11-17 October, **Marine Sciences in the Red Sea**, Al-Ghardaqa (Prof. H. A. F. Gohar, 101 Kasr Al-Ainy, St, Cairo, Egypt).

12 October, **Mutagenicity Testing**, London (Mr M. L. Richardson, c/o Mr E. A. Taylor, The Royal Society of Chemistry, Burlington House, London W1, UK).

18-31 October, **Chemical Carcinogenesis**, Erice-Trapani (Dr S. Parodi, Istituto Scientifico per lo Studio e la Cura dei Tumori, Viale Benedetto XV, 10-16132 Genova, Italy).

19-23 October, **Concrete Roads**, London (The Concrete Society, Terminal House, Grosvenor Gardens, London SW1, UK).

26-30 October, **Artificial and Human Intelligence**, Lyon (Dr A. Elithorn, The Royal Free Hospital, Pond St, London SW3, UK).

27-29 October, **Petroanalysis**, London (Miss I. A. McCann, Institute of Petroleum, 61 New Cavendish St, London W1, UK).

GUIDE TO AUTHORS

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusion in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should be identified in the margin on their first appearance. Equations should occupy single lines if possible: $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on halftones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

19 March 1981

US versus science education

The first Reagan budget, well advertised in advance as a device for getting the government off the taxpayer's back and the taxman out of his pocket, has more than lived up to expectations in its mean view of science education, at least as administered by the National Science Foundation. Ever since the heady post-sputnik days, when Washington was thronged with committees giving the Eisenhower Administration advice on how best to meet this unexpected challenge to American technology, the National Science Foundation has been spending a sizeable part of its budget (but still a modest annual sum) on the support of curriculum development in schools and colleges. It can boast of having done more good than foolish works. Zacharias's organization, the Physical Sciences Study Committee, may not have produced the ideal physics curriculum for the average high school, but it was a cheerful demonstration that distinguished academics were willing and able to help with the problems of teaching in the schools. And many young people (not only in the United States) learned a great deal of physics from the textbooks, readers and experiments that the committee devised. In retrospect, however, it may have been even more telling that the experiment proved infectious. Quite soon, in the early 1960s, an army of high-school teachers and a battalion of academics were caught up in the network of committees dedicated to the improvement of science teaching.

Inevitably, there have been excesses and mistakes. If the foundation was less confident in the development of curricula in the social sciences and the humanities than in the physical or biological sciences, it should not shoulder all the blame. Mere money is not sufficient to design a good curriculum. The essential is that good teachers and perceptive academics should be willing, and that school systems should help with administration and facilities. In any case, what matters is not that such and such a set of books should be written as an integrated package (and then, with luck, adopted in the Californian schools) but that teachers should have learned that continual change is necessary but also

possible. The \$13 million the foundation spent on these modest efforts last year will not go far to help the US Treasury to balance its books (or, rather, to live with a deficit of \$41,000 million). Cutting back on this part of the foundation's programme when the high schools are painfully aware of the need for new kinds of teaching seems either unwise or spiteful. Or is the Administration calculating that with Mr Walter Cronkite's new science programme advertised on CBS for the summer, the National Science Foundation can fade gracefully from the scene?

The budget request will also cut the foundation's modest support for students of science and engineering, mostly at the graduate level. The timing is entirely misplaced. Only a few months ago, the Carter Administration was agonizing about the problems of recruiting good people into engineering and especially engineering education. The problem cannot have disappeared since Inauguration Day. And in spite of the largely self-sustained character of American students — the envy of British university administrators (see below) — the United States government is probably still getting value for money from its spending on this good cause. Any Presidential Science Advisor would vouch for that, which may be one of the reasons why President Reagan appears reluctant to appoint such a person.

One of the temptations that afflict incoming administrations everywhere is that of abolishing at least some pre-existing institutions. The National Science Foundation's education programme is a natural candidate for this treatment. What it has been doing is what the market might otherwise have to do. It is also an administrative inconvenience that there should be an organization concerned with education entirely separate from the Department of Education. And for all their clubbiness, people interested in such things as curriculum development do not constitute a constituency of any importance. So why not abolish the institution? The irony, which other administrations have found to their cost, is how often it is necessary to recreate a substitute of some kind.

. . . . and UK versus universities

British universities, after too many months of somnolence, have taken fright. Last week, Sir Alec Merrison, Vice-Chancellor of the University of Bristol but speaking in his capacity as chairman of the Committee of Vice-Chancellors and Principals, accused the government of "a kind of madness". He and a posse of fellow vice-chancellors seem privately to have told the Secretary of State for Education and Science, Mr Mark Carlisle, much the same; by Merrison's account, they made no impression with their complaints that the British government is "profoundly misguided" in its intention to cut state support for the university system by 8.5 per cent in the next three years. Together with the switch to full economic fees for overseas students now under way, state support for the British university system will have fallen by at least 11 per cent, and perhaps by 15 per cent, by the academic year beginning in 1983. Either way, structural changes of some kind will be forced on the system. It is no wonder that people have taken to strong language.

Universities themselves must, however, shoulder some of the responsibility for what is now in prospect. At least since the summer of 1978 (under a different government), it has been clear that structural change was unavoidable. Even the now forgotten promise of "level funding" would not have allowed universities

to keep on recruiting young people to academic posts at a sufficient rate to stay intellectually alive, also competitive. The age distribution of people in tenured posts, skewed by the rapid recruitment in the 1960s of then young academics, ensures that in the 1980s the rate of retirement among British academics (now one per cent a year) will be less than a third of that needed to permit recruitment at a rate corresponding to a steady state. British universities have talked at length about the problem; none has found a solution. The government's decision, two years ago, that universities must collect larger tuition fees from overseas than from home students, whose first effects are becoming apparent only in this academic year, has had the effect of distributing penury at random. Again, most universities have put on hair shirts to wait for whatever the fates might bring. The outstanding exception is the London School of Economics, which has actually increased the number of its new overseas customers by the simple expedient of telling prospective students (and their governments) about its own virtues. The new cut goes deeper. The government intends simply to take cash out of the system, and there is no alternative source in sight. The damage that will be done would have been more easily contained if the university system had responded much more imaginatively to the previous

crises. There has been plenty of warning.

The government's behaviour is even less creditable, but consistent with its brief record. Overseas students' fees were increased by fiat, without consultation (and without much thought). The result is not merely the arbitrariness with which different universities are affected but the patchwork of petty anomalies and injustices with which university administrators have to struggle. The latest cut has been deviously introduced. Last December, when the government casually announced a cut of 3.5 per cent in next year's budget, nobody mentioned that there was worse to come. And last week the announcement of two further instalments (in 1982 and 1983) was tucked away in the Treasury's annual forecast of government expenditure. Was somebody hoping that nobody would notice? Or that the issue would be subsumed in the generalized sense of grievance which this year's higher taxes have evoked? Whatever the truth, there seems to have been only the most cursory consultation with the universities about the consequences of the new cuts and no serious attempt to discover the least damaging ways of saving money. In short, there is no explicit policy for the universities. On all the evidence, there seems not even to be a secret policy. Ministries involved with higher education utter threats and then, several weeks later, deny them with reassuring promises. A few weeks ago, for example, the government had given the universities to understand that they should not try to solve their money problems by taking in extra students; last week's documents on spending promises that they can take as many as they can teach. Is it not time that Parliament forced the government to say what is in its mind? Have the universities no friends left at Westminster?

Ironically, the academic community is probably as keenly aware of the government's economic problems as any other in British society, with the possible exception of the bankers, themselves afflicted by a retrospective capital levy in this year's British budget. The government's central objective is to borrow less from the commercial markets, to which end spending less is important. The new cuts will yield £80 million a year and the increased fees for overseas students nearly as much. However the "saving" is shared out among the British universities, the consequences will be bad for the quality of British university education. The government's expenditure plan says laconically (in a one-sentence paragraph) that "the plans assume a significant tightening of staffing standards", which is a euphemism for a further decline in the ratio of teachers to students. The plan also says that the universities collectively will admit fewer students in the years ahead. The plain implication is that the system will have to shed teachers. That, in the last resort, is why the vice-chancellors are up in arms.

So how should the universities respond? As they should have done in the previous crises of the past three years, by organizing themselves for flexibility. With a few exceptions, the objectives of most university institutions in Britain are similar — the pursuit of the highest academic standards in the teaching of undergraduates and of excellence in research. For most universities and almost all academics, the ideal is Oxbridge. And there is very little encouragement, in the way the government subvention is disbursed on the recommendations of the University Grants Committee, for them to aim at distinctive goals. The result is that too many British universities are trying to do the same things with such inappropriate resources that they are bound to fail.

Would it not, however, be preferable that they should aim at excellence in what they already do well? The system includes half a dozen institutions which are what would be called liberal arts colleges in the United States but which nevertheless waste endless time and money on graduate education in the traditional pattern without recognizing that their graduate schools will always be too small to be viable. It would be better for the institutions concerned, their students and the system as a whole, if this were recognized. The strong civic universities in Britain, foundations of the late nineteenth century, are another distinctive category of universities. Not so long ago, they drew a great deal of strength (and substantial amounts of cash) from the cities in which they were sited. Although local loyalties are still in many places strong,

they are nowhere as strong as they used to be when it was no shame for a young person to become a student at the nearest university. In the serious crisis about to inflict itself on them, the civic universities will regret the way that the old loyalties have been eroded. Some of them may even find themselves in sneaking sympathy with the plan which the government is said to be hatching for replacing the present system of maintenance grants for students (over and above tuition fees) with a smaller grant and the offer of a loan. There could hardly be a better device for channelling students towards the nearest university, while stronger local links would give these universities opportunities to increase their present interest in the retraining of local adults — professionals, technicians, even craftsmen.

The benefits of reorganization for diversity are several, not least the direct economies there would be once the universities stopped aping each other. In such a pattern, the system could hope to match courses to students more expertly than at present, while a clear knowledge of their distinctive roles would make it possible for individual institutions to tell a more convincing tale when asked (as they will be frequently in the years ahead) why they continue to exist. But how is such a pattern (or any other pattern) to be brought about? The conventional wisdom among academics is that universities are so incapable of making long-term policy, and of imposing change upon themselves, that change must be forced from outside, either by the University Grants Committee or by some seemingly impartial committee made up of academics from elsewhere. This is too depressed a view.

Although the occasions in the past when individual universities have changed radically have been times of plenty, there is no reason why the penury now in prospect should not also be a spur to change. Sheer self-interest dictates that it should be, but the University Grants Committee could do much to help. Institutions willing to take painful steps — closing, say, a particular department, or all graduate schools — need and deserve compensation. The snag, in present circumstances, is that an institution making substantial savings in its internal operations cannot be sure that it will benefit in the long run. The University Grants Committee can always in its wisdom recommend that the funds should be spent elsewhere in the system. So would it not make sense, for the duration of whatever transitional period lies ahead, that institutions making voluntary sacrifices should benefit from some kind of salve for their wounds? The University Grants Committee, more used to sharing resources according to its own hidden definitions of equity, is not used to the encouragement of entrepreneurship. But even the University Grants Committee will have to change before this crisis is over.

So too will many other institutions. Even if the outcome of the next few years is a concentration of graduate education in a subset of the universities, it would be intolerable if academics and graduating students from elsewhere were denied opportunities for research. This would require that sources of research support, the research councils in particular, should change. Then, given the need for compatibility within a mobile and diversified system, most universities would find it necessary to restructure their undergraduate curricula. Many, no doubt, would rediscover the virtues of the four-year undergraduate courses, of less specialized (if still competitive) entry requirements and of less narrow courses of study. In other words, there may be benefits in the present adversity.

In the wake of last week's shock to British universities, many dispondent academics will consider this cheerful outcome a delusion. Is it not more likely, they will ask, that the University Grants Committee will recommend that misery should be evenly distributed, with the result that all universities become less good? That, certainly, is possible. It is, however, unlikely that all universities within the system will be equally passive. When they have recovered their breath, the strongest among the universities will be thinking of how to secure for themselves a greater measure of independence than they have enjoyed for years. In due course, all those that survive will follow suit. For what the latest crisis in the British system shows is that universities, jealous of their claims to autonomy, are safest when they are also independent.

Kiss of life for Clinch River breeder

Reagan ditches Carter policy on proliferation

Washington

Despite the objections of his economic advisers, President Ronald Reagan has decided to pay off some of his political debts by letting construction work begin on the liquid metal fast-breeder reactor at Clinch River in Tennessee, which critics claim is both economically unnecessary and technically out of date. However, Mr Reagan is holding back from providing further federal support for the reprocessing of spent nuclear fuel until it becomes clear whether the private sector is prepared to take on this responsibility.

Both the fast breeder programme and commercial spent-fuel reprocessing had been held in check by President Carter on the grounds that they contributed to the growth of the "plutonium economy" and thus raised the risk of the proliferation of nuclear weapons. But both decisions have come under strong attack from the nuclear industry as an unnecessary restriction on the growth of nuclear power, an attitude known to be held by the new Energy Secretary.

In his budget request to Congress, the full details of which were released last week, President Reagan is requesting a total of \$737 million for support of fast-breeder research in the fiscal year 1982. A substantial proportion of this increase will go towards the start of construction work on the Clinch River reactor as a "demonstration project". Development funds have already paid for the design and much of the component fabrication, but construction had previously been held up by President Carter's request to the Nuclear Regulatory Commission not to issue a construction licence.

The Clinch River reactor has a high symbolic value for the US nuclear industry. Many used it to focus their opposition to Mr Carter's general non-proliferation policies. Others argued against the Carter Administration's conclusion that the declining rate of increase in the demand for electricity, and a short-term surplus in domestic uranium supplies, reduced the need for an intensive breeder development programme.

Environmentalists now point out that they have a new — and perhaps surprising — ally, Mr David Stockman, director of the Office of Management and Budget and the chief architect of Mr Reagan's austerity budget. Using the same arguments put forward by the Carter Administration, Mr Stockman circulated a letter to fellow con-

gressmen in 1977 describing plans to subsidize the construction of the Clinch River reactor as "totally incompatible with the free market approach to energy policy".

Critics of fast-breeder reactors, such as the Natural Resources Defense Council, claim that in order to find the money for increased spending on nuclear programmes in general, including the liquid metal fast-breeder reactor, the Department of Energy is intending to cut back significantly in research and development on alternative energy sources. It is proposed to cut the solar energy research budget, for example, from \$625 million in 1981 to \$241 million in 1982, and research and development in conservation from \$558 to \$195 million, while research on fission reactors would increase from \$1,166 to \$1,247 million.

Even the Office of Management and Budget is said to have argued that there is

an inconsistency in cutting off support for "demonstration" projects in solar and fossil energy, while supporting just such an approach for fast breeders; Mr Stockman is said to have put up a fierce battle against Clinch River funding, although he was less opposed to the increased budget request for design work on a larger, more advanced fast breeder.

In a report published by the subcommittee last week, a former member who left Congress last autumn, Republican congressman John Wydler of New York, reported on a visit to the British fast breeder programme, and used the British (and French) experience to bolster his argument that completion of Clinch River is the logical next step for the United States.

Mr Wydler also reported that British scientists were attracted to the idea of cooperation with the United States, a move

British academics up in arms

British universities were in a state of shock last week after the government's announcement of its spending plans for the next three years. Spending on home students is to be cut by 8 per cent in real terms by 1983–84. The Committee of Vice-Chancellors and Principals estimates that the total reduction in university income could be as high as 15 per cent when the shortfall in overseas students, expected after the government's decision to charge them economic fees, is taken into account. Sir Alec Merrison, chairman of the Committee of Vice-Chancellors, last week described the expenditure plan as madness. He said he was not aware that the government was reducing the universities' grant for any reason other than saving public money.

The cuts will undoubtedly force the universities to review the services they can offer, which is a fact acknowledged by the government in its white paper on expenditure published on budget day, 10 March. The vice-chancellors and the University Grants Committee seem to have persuaded the Secretary of State for Education that money should be set aside for the scaling down operation. But, instead of making more money available, as the universities must have hoped, the government announced on 13 March that £20 million should be taken out of the 1981–82 recurrent grant — at £979 million already 3 per cent less than for 1980–81 — for the purpose.

The Committee of Vice-Chancellors estimates that making necessary economies could be more expensive than maintaining the universities at their present level. The problem is that after several years of static budgets, further economies cannot be made without reducing staff. Salaries and related costs at present consume 72 per cent of the recurrent grant, more than half of

that going on academic pay. Redundancies, which would break the contracts of employment of tenured academics (approximately 80 per cent hold tenure), would involve the universities in costly litigation and large redundancy payments. And the committee's estimate that one in eight jobs will have to go would certainly mean the closure of departments and possibly entire universities. Nobody yet knows whether the £20 million set aside will be enough to help meet these costs.

The University Grants Committee will begin dividing what money there is between institutions in May. It is not thought to

"Madness" says Merrison

favour cutting any university's grant completely, but neither does it want to spread the money too thinly. Possible alternatives are to close selected departments — a new move for the committee, which normally leaves individual universities to run their own affairs — or to restructure the system, leaving some universities to develop as centres of excellence and turning others into something akin to American liberal arts colleges. The trouble is that the committee has never had to be so *dirigiste* in the past and has not formed a proper mechanism to take the necessary decisions.

Judy Redfearn

which had previously been endorsed by the committee, particularly because of problems with leakage in the existing British fast reactor steam generator components. Mr Wydler also said, however, that UK Atomic Energy Authority officials felt that cooperative agreements with the United States presented unique difficulties because of the Freedom of Information Act and the Atomic Energy Act requiring the disclosure of proprietary business information.

In contrast with his defeat in the fast breeder debate, Mr Stockman seems to have won on the other point of dispute with nuclear advocates in the Department of Energy, namely renewed federal support for spent fuel reprocessing from commercial reactors. The nuclear industry has been pushing for the reopening of the Barnwell reprocessing plant in South Carolina, which was denied funds by the Carter Administration; no money for commercial reprocessing is, however, included in the budget request, although there are funds for the West Valley Demonstration Project.

Backing up its general stance in favour of reprocessing, however, the Reagan Administration has decided to discontinue the spent-fuel programme intended to provide storage facilities away from power station sites. This programme is being refocused within the Department of Energy to concentrate on the development of alternative spent-fuel storage technologies which can be used by utilities at existing reactor sites.

Although the Administration has set its face against subsidies for commercial reprocessing, it has in the past few days become known that plans to dismantle at least this aspect of the Carter anti-proliferation policy are being worked out.

David Dickson

German big science

Win some, lose some

Germany should spend an extra DM 800 million (£170 million) on big science projects over the next ten years, recommends the committee set up a year ago by the previous minister of science, Volker Hauff — and another DM 425 million of projects should be accounted for under the current budget.

The "big science" committee, chaired by Professor Klaus Pinkau (who was recently appointed director of the Max Planck Institut für Plasmaphysik at Garching) reported last week to Minister Andreas von Bülow on a shopping list of ten major projects (*Nature* 3 July 1980, p.8) ranging from high-energy physics to geology, which, if they were all undertaken now, would have cost Germany at least DM 2,015 million (430 million). On being given the task, Pinkau said it would be a "work of art" to steer the right course between scientific worthiness and the government's

ability to pay — for the committee was given no financial guidelines. In the interim, the German economy has weakened, and the Pinkau committee felt obliged to take cost strongly into account.

However, some sleight of hand reduces the bill. The committee recommends that Germany support LEP, the large electron-positron collider which physicists would like to see as the next major facility at CERN, the European subnuclear physics laboratory in Geneva. LEP will cost Germany DM 350 million; but as it is likely to be built within CERN's current budget and staff, the committee reckons it will mean no extra expenditure. Similarly, a DM 75 million replacement for Meteor, Germany's principal and ageing oceanographic research vessel, can be paid for within the current geosciences budget.

Of the other projects, the committee says the refitting and expansion of the BER II research reactor at the Hahn-Meitner Institut, Berlin, costing DM 47 million, should be undertaken immediately; so should the construction of the DM 33 million SUSE, a 250 MeV superconducting cyclotron for heavy ion physics proposed by the Technical University of Munich — provided the university can raise part-finance from the regional government of Bavaria, and make the accelerator a national facility. An equivalent facility proposed by the Jülich nuclear laboratory near Cologne was rejected (it cost more).

The committee puts some of the most expensive projects on ice. HERA, a high energy proton-electron collider for the DESY subnuclear physics laboratory at Hamburg which would cost DM 600 million (in two parts) is recommended "in principle", but a decision should await developments in superconducting technology; and the question of a relativistic heavy ion accelerator for GSI Darmstadt (DM 190 million) is to "remain open".

The latter raises an interesting question in physics: will relativistic heavy ion collisions lead to entirely new states of nuclear matter (as in neutron stars) as some nuclear physicists predict, or will it just lead to a mass of high energy but otherwise familiar fragments? The feeling in Germany is that some low cost test of this question should be made first, for example, by feeding heavy ions into the intersecting storage rings at CERN. But if such experiments were done, German thinking goes, it should be *outside* CERN's budget or there will be no money for LEP.

On this issue, on HERA, and on others such as the proposed spallation neutron source (where Jülich and Karlsruhe have competing proposals) and the deep drilling programme of the Deutsches Forschungsgemeinschaft, Germany will also be looking for increased international collaboration. The European synchrotron radiation source, however, proposed by the European Science Foundation, is said to be "not of high priority". Robert Walgate

Madrid conference

Detente denied

Western leaders have failed to react "realistically" to Mr Brezhnev's latest proposals for detente, a *Pravda* editorial complained last week. The proposals, put forward at the party congress last month, covered three main issues: the extension of "confidence building measures" (CBMs) to all Soviet territory west of the Urals, and the possibility of introducing similar measures in the Far East, special negotiations on the Persian Gulf and Afghanistan, and a moratorium on medium-range nuclear weapons in Europe.

The party congress coincided with the closing weeks of the Madrid review conference on implementation of the Helsinki Final Act. CBMs, as specified in the Final Act, cover notification of major military manoeuvres (more than 25,000 troops), exchange of observers for manoeuvres and also notification of major troop movements, though this last clause is left to the discretion of the participating states. Notification of manoeuvres, moreover, in the case of a participating state whose territory extends beyond Europe, is mandatory only for an area within 250 km of its European frontier. The suggestions that the Helsinki clauses on CBMs should extend as far as the Urals, came, initially, from the French delegates to Madrid, and were not greeted with enthusiasm by the Soviet delegation, until, on 23 February, Mr Brezhnev made them his own. Not surprisingly, Mr Brezhnev suggested some kind of reciprocity from the West. Since the whole of Europe falls within the CBM zone, this would presumably have to be of a qualitative nature, such as the discretionary notification of smaller-scale troop movements, or, judging from hints in the Soviet media, curtailing "provocative" broadcasts to the Soviet bloc.

Afghanistan, too, was an issue which the Soviet delegation at Madrid at first tried to block as "irrelevant" (because the Helsinki Final Act referred to security and cooperation in Europe). Mr Brezhnev's call for a moratorium on nuclear arms seems to reiterate the Polish proposal at Madrid for a European disarmament conference in autumn 1981. Unfortunately, none of Mr Brezhnev's peace proposals touched on the sensitive issue of declaration and verification of troop and armaments strength — the point on which all similar negotiations have broken down for the past 35 years. His suggestion of an "authoritative international committee" whose members "might include the most prominent scientists" of the countries concerned, which would "demonstrate the vital necessity of averting a nuclear catastrophe" has, however, been passed on to the international Pugwash council as a matter of urgency.

On the other aspects of detente, the

Moscow seminar threat

The Moscow Sunday seminars for Jewish refusenik scientists, which have been held (official harassment permitting) since 1973, now face a new threat. Last Friday, Dr Irina Brailovskaya was informed by the deputy chairman of the local municipal council that if she continued to host the seminars, she and her whole family would be liable to internal exile.

This official told Dr Brailovskaya that there had been complaints from the neighbours about the holding of the seminars. "We do not object to scientific meetings", he explained, "but the devil only knows what is going on here!"

The seminars have only recently resumed after a KGB clamp-down last autumn. Following the arrest of Dr Viktor Brailovskii, on 13 November, for several weeks the apartment was surrounded on Sundays by security police who turned away intending participants. Early in the new year, the seminars resumed on Saturday evenings, and then, a few weeks ago, reverted to the traditional Sundays.

In a recent message to Western scientists, Dr Brailovskaya said that her husband has been held in custody beyond the legal limit (three months) within which he should have been either charged or released. He is, she said, in a poor state of health, suffering from chronic hepatitis and a blockage of the gall duct.

auspices seem good for renewed East-West cooperation. President Reagan's assistant secretary designate on human rights, Dr Ernest Lefever, is reported to favour keeping such matters distinct from international politics. The several thousand Western scientists who signed personal moratoria pledges bound themselves to limit their contacts with the Soviet Union only until the end of the Madrid conference. However, at the meeting of the United Nations human rights commission in Geneva last week, a motion from the Canadian delegation was dropped from the agenda.

Vera Rich

Science education

Tap turned off

Washington

The Reagan Administration is proposing to eliminate all support at US universities for undergraduate and graduate science students at present provided by the National Science Foundation.

The cuts are part of a plan to phase out the foundation's responsibilities for science and engineering education, justified by the claim that these are of lower priority than the need to support basic research. But the proposed cuts may have been partially instigated by conservatives upset by some of the foundation's educational activities.

The cuts would eliminate several programmes introduced over the past few years, primarily at the direction of Congress. These include support for women, minorities and "talented individuals" in science, strengthening science teaching in middle and high schools, and efforts to improve public understanding of science.

The new Administration argues that such efforts are of low priority, and that they are too broadly spread and narrowly focused to have any significant effect. Science teaching has, however, always been treated better by Congress than by either the National Science Foundation itself or the Office of Management and Budget; and there remains a good chance that some of the money will be put back during the congressional review process.

In response to the report last year by the foundation and the Department of Education which drew attention to the growing "scientific illiteracy" among the US public and to concern over the lack of adequate technical graduates in fields related to energy and military technology, President Carter had proposed in January that the 1982 budget for the foundation should include an allocation of \$119.9 million for science and engineering education, a significant increase over the \$80.7 million allocated in the current year.

In contrast, the new Administration suggests that the current budget be reduced to \$64.7 million, and that support for science and engineering education next year be reduced to \$9.9 million. All of this sum would be used to meet existing commitments to students receiving fellowships.

Other cutbacks include the elimination of three major programmes: science education resources improvement (\$21.8 million in 1980), aimed at improving undergraduate instruction in two- and four-year colleges by upgrading instructional equipment and teacher competency; science education development and research (\$13.8 million) for developing new and more effective materials and methods of instruction in science and engineering; and science education communication (\$8.5 million).

Reaction to the proposed cuts has been sharp. Dr Alan Bromley, professor of physics at Yale University and president of the American Association for the Advancement of Science, warned that "to expect scientific and technological progress while abandoning efforts at improving science and engineering teaching in our schools is illogical and a disservice to the nation's interest". The association had previously announced that science education was to become a principal target of its own efforts over the coming year.

Dr Gerald Lieberman, dean of research at Stanford University, last week voiced the universities' anxieties: "In the past we have had to put little of our general funds to the support of graduate students in

Argentinians face charges

Dr Jose Federico Westerkamp, formerly professor of physics at the University of Buenos Aires, was arrested on 27 February 1981 during a police raid on the human rights organization CELS (Centro de Estudios Legales y Sociales, Centre for Social and Legal Studies). He was held in custody for a week, then released. Police investigations into his human rights activities are, however, continuing.

Dr Westerkamp, who had been active on behalf of human rights in Argentina for several years, was a co-founder of CELS, together with two lawyers — Dr Emilio Fermin Mignione and Dr Augusto Conte Mac Donell. The group, which was set up early in 1979 and legally registered in March 1980, investigates human rights abuses, including the defence of political prisoners and the gathering of data on "disappeared" persons. Dr Westerkamp, whose son Gustavo has been a political prisoner since 1975, has been particularly active on behalf of imprisoned and "disappeared" scientists and academics, and has on numerous occasions spoken on their behalf at international scientific meetings.

According to the Argentinian newspaper, *La Razon*, CELS members face charges under article 224 for possessing plans and diagrams of military installations, carrying a possible penalty of two to eight years imprisonment.

science and engineering, but it is likely that we will now have to reevaluate our whole policy in this area". Dr John C. Crowley, of the Association of American Universities, claims that the cuts would wipe out "one of the two functions for which the foundation was established" and "calls into question the basic purpose of the National Science Foundation".

At the foundation itself, where it has been frequently claimed that science education has received less support than basic research, officials admitted that the cuts were "hard to square" with the report presented to President Carter last autumn.

Federally-sponsored science education programmes have some powerful opponents on the right. Some argue that, in principle, the federal government should play a minimal role in curriculum development, leaving it to state and local schools boards; others have criticized the foundation's education activities in the past, for example in developing biology and social science courses which, they claim, reinforce "relativist" values by portraying man and woman as part of nature, rather than unique creations. The cuts in the science education budget seem to have been orchestrated by groups such as the conservative Heritage Foundation and are likely to receive support from conservative members of Congress.

David Dickson

Swiss nuclear power

Sanctions bite

Zurich

There is growing concern in Switzerland about uranium supplies for the nuclear energy programme. Indigenous deposits are too small to reduce foreign dependence, and the efforts of the chief suppliers, Canada and the United States, to prevent nuclear proliferation have led to acts which the Swiss consider to verge on blackmail. Although the pro-nuclear lobby maintains that the long-term prospects are "not unfavourable" and that the present supply hitch is merely a temporary inconvenience, there are signs that the country's independence, self-determination and neutrality will be threatened if nuclear power becomes a major element in its energy mix — just as today they are threatened by an overwhelming dependence on imported oil.

The nuclear plan — yet to go through parliament — foresees a capacity of about 7,000 MWe in conventional nuclear reactors by the beginning of the next century. With an average reactor life of 30 years, total requirements of uranium will be around 40,000 tonnes. A laborious search for indigenous deposits over the past 20 years has turned up several occurrences of interest, none of them economically viable.

The highest grade mineralizations occur in the Vallorcine granite in the Vallée du Trient (Valais) with average uranium contents of 0.1 to 0.2 per cent. But extensive exploratory drilling and trial shafts revealed reserves of less than 2,000 tonnes. Larger reserves are suspected in the upper Rhine valley near Trun (Graubünden), but there the average grade is too small (0.02–0.1 per cent). An unpublished government report in 1977, after an initial exploration costing 6 million francs (£1 = SF 4.33), concluded that the deposits in the Alps can be regarded only as emergency reserves. Normally, Swiss reactors will be completely dependent on imported fuel. It is this dependence which is beginning to cause some alarm.

The present dispute with Canada illustrates the issues. Since 1958, Canada has been the main supplier of natural uranium under a bilateral treaty. In 1977, however, the Canadian government refused permission for the transfer of yellow cake to the fuel fabrication plants in the United States which the Swiss utilities had already paid for. Since then, almost 1,000 tonnes of uranium have been blocked, and the Swiss utilities have been forced to buy alternative supplies on the international market — at far higher prices.

The reason for the blockade is the reluctance of the Swiss government to give in to Canada's demand for inspection and control rights with respect to some Swiss exports. Since the explosion of an Indian nuclear device in 1974, Canada has insisted

that every effort must be made to prevent sensitive materials, goods and technologies of "essentially" Canadian origin from being passed on to third countries without Canadian permission.

The Swiss government is in an extremely awkward position. The Bundesrat is being pressured from all sides and is still vacillating. The utilities consider Canada as their main long-term supplier and want the Canadian demands to be met at once, with as little fuss as possible. In fact, they have already negotiated the required amendments to the treaty, with rather furtive government backing. But this document has been gathering dust since 1979 because of its political explosiveness. The opposition by industrialists and politicians to a treaty modified under duress is expected to be loud and strong. The former see it as a completely unwarranted interference in the free market and object to controls not governed by Swiss laws. The latter see the loss of sovereignty and capitulation to outside pressure as matters of principle. Jurists have even suggested that Canada's failure to supply is a breach of the treaty which should be taken to the international courts — an interpretation which the Bundesrat has vehemently denied. And anti-nuclear members insist on asking awkward questions in parliament.

The general public, which is already rather sceptical of the future of nuclear energy, is confused. Industry and government experts maintain that the situation is under control and that it is only an initial

difficulty which, once mastered, will be followed by long-term guarantees of fuel supply. International cooperation and the direct financial participation of the utilities in uranium exploration will, they say, ensure that future requirements will be met. But the signs are hardly encouraging.

Two tendencies suggest that uranium mining and export will become increasingly controversial issues in the internal politics of the producing countries — the inevitable exploitation of lower grade ores, resulting in greatly increased environmental impact, and the increasing concern about the spread of nuclear weapons. The rapid development of nuclear power elsewhere will keep the world uranium market under pressure — and minor users like Switzerland at a constant disadvantage. If Switzerland's uranium supply today is being adversely affected by the explosion of a bomb nine years ago on another continent, what next?

Geoff Milnes

Indian community health

Cure for all ills

Lucknow

The Indian government's target of "health for all" by the year 2000 will not be met unless present policies are radically changed, according to a study group set up by the Indian Council of Medical Research (ICMR) and the Indian Council of Social Science Research (ICSSR).

Their report stresses that health should be recognized as a function of the overall development of society. An "alternative health care model" is presented which includes programmes for national economic growth with the objective of doubling national income per capita by the year 2000, full-scale employment at reasonable wages, improvement in the status of women, adult education, elementary education for all children between 6 and 14, welfare of backward classes, rural electrification, housing and organization of the poor. The report also suggests setting up a National Population Commission with the objective of stabilizing the total population at 1,200 million by the year 2050.

The "alternative health care model" encompasses promotive, preventive and curative aspects and combines "the valuable elements in Indian culture and tradition with the best elements of the Western system".

The report suggests that a Medical and Health Commission should be set up to look after the quantitative and qualitative aspects of health education. It recommends that drug production should be correlated with disease patterns with a bias towards the economic production of basic and essential drugs. On the research side, the important areas are delineated as parasitic diseases, problems of environment, sanitation and indigenous medicine.

Zaka Imam

More interferon cloned

The interferon genes of α and β interferon, produced respectively by lymphocytes and fibroblasts, have been cloned successfully in *Escherichia coli* at the University of Warwick, according to an announcement this week from the university. The project, led by Professor D.C. Burke, has been under way for the past three years. The Wellcome Foundation, one of several sources of finance, is also collaborating technically.

Although the two interferon genes have been successfully cloned in a bacterial plasmid, the genes have not yet been incorporated at plasmid sites where they are expressed, so as to produce the protein interferons.

Although at least three other groups (Biogen, Genentech and G.D. Searle) have successfully cloned interferons, doubts about the patentability of the techniques imply that being fourth is not necessarily to be robbed of reward.

For cloners of interferon, however, the most obvious prize for the immediate future is the cloning of gamma-interferon, otherwise known as immune interferon, which may have more interesting physiological properties than the two now in clinical trials.

Oil tanker hazards

Inaction at sea

Brussels

The recently published Liberian report on the *Amoco Cadiz* disaster draws attention to the belief widely held in shipping circles that 80 per cent of accidents at sea are due to human error. In March 1978 the tanker went aground off the coast of Brittany spilling 230,000 tonnes of oil. And now the captain is to get his licence back despite his failure to send out a distress signal at the earliest opportunity.

Amoco Cadiz — what happens next time?

The incident prompted the European Commission to spend two and a half years in preparing a set of proposals on how such accidents could be prevented and cleaned up in the future. The proposals were published last June, and despite pressures from the French government they run the risk of never being accepted.

The most controversial issue concerns a requirement that member states should identify sub-standard ships using their own ports and order deficiencies to be rectified. Now that Greece has joined the European Community, 30 per cent of the world's shipping falls under Community jurisdiction. A recent debate in the European Parliament on the idea that the port state should check the standards of shipping ended in uproar, with the Greek representatives defending themselves against accusations that most defective ships were Greek-owned.

Conventions on shipping safety have already been established by the Inter-governmental Maritime Consultative Organization (IMCO), but signatory countries have been slow to enforce them. The Commission's directive would make the IMCO conventions mandatory.

Dissatisfaction at the slow progress of both IMCO and European Commission proposals led France to hold a conference on shipping safety and pollution in

December last year. The Paris conference, which was attended by Spain, Portugal and Nordic countries as well as the European Community, set up a committee, which has been meeting in the Hague, with the declared aim of drawing up rules on the obligations of port states which would be acceptable to all European countries.

While these deliberations go on, the European Commission has made still more proposals, intended to stand more chance of being adopted quickly. One directive, already adopted, calls for all relevant data on tankers and their movements to be

stored on a computer. Another requires details of the contingency plans of all member states to be computerized, and the Commission wants to run training schemes and equipment testing programmes. Many such precautions are already in operation in the United States, causing operators with sub-standard ships to concentrate on European trade.

Whatever the various European Community bodies decide, nothing much is likely to happen for some time. The United Kingdom and Denmark still refuse to countenance giving the Community competence in this field.

In the meantime, France is still pressing for the £670 million estimated to be the cost of damages caused by the *Amoco Cadiz*.

Jasper Becker

US animal research

Stricter safeguards

Washington

Although the United States has so far avoided violent demonstrations against the use of animals in research such as those in Canada and the United Kingdom, public pressure for stricter safeguards is mounting. Three separate bills have been introduced in the new session of Congress. One, first introduced by Representative

Frederick Richmond in 1979, would permit the withdrawal of public funds from any research project in which laboratory animals were judged to be used unnecessarily.

The research community, and officials at the National Institutes of Health (NIH), are dismayed at the prospect of new regulations. At a meeting last month convened by NIH, scientists and animal welfare groups discussed the feasibility of the wider use of *in vitro* testing methods and mathematical modelling as alternatives to the use of live animals. Dr William Raub, associate director at NIH, said that he would approach the Office of Science and Technology Policy (if it survives under the new Administration) to suggest a regular forum for the discussion of alternatives to animals.

This proposal should at least satisfy Congressman George Brown, previously chairman of the House of Representatives Science and Research Committee, who came out in favour of more open discussion between scientists and their critics after a flood of correspondence supporting the Richmond bill. One of Mr Brown's objectives is to avoid trouble such as that in Canada, where radical anti-vivisectionists last year broke into National Research Council laboratories, setting free laboratory animals.

In the United States, protests against the widespread use of laboratory animals have taken the form of lobbying, led by groups such as United Action for Animals, based in New York.

One result so far stems from the campaign last year by more than 400 animal welfare groups against the Draize irritancy test for cosmetics, in which liquids are dropped on rabbits' eyes to test for inflammation. Revlon, one of the largest cosmetic manufacturers, was singled out for criticism and last November gave a \$750,000 grant to Rockefeller University to investigate cell culture alternatives.

The passage of new legislation will not, however, be straightforward. Present legislation goes back to the 1960s and is concerned with the care of laboratory animals, not with the tests to which they are subjected. The Scientists' Center for Animal Welfare is pressing for the wider adoption of a procedure already introduced by the Veterans Administration in which research proposals are vetted in advance to ensure that appropriate procedures are followed in the use of laboratory animals.

Mr Richmond's bill, the front runner in Congress, would establish a centre for the development of methods of research and testing not involving the use of live animals. Supporters of the bill say that such a centre could operate in much the same way as the National Toxicological Program, introduced three years ago, which coordinates research on toxic substances in the major federal agencies. The centre would have power to direct between

30 and 50 per cent of NIH funds for animal-based research into the development of alternative testing methods.

Critics, such as the National Society for Medical Research, argue that the bill would give federal regulators "potentially catastrophic" powers and that scientists use alternative methods voluntarily when they are available. Feelings on both sides run high, however. NIH officials, previously cool to the demands of the animal welfare groups, seem now to be hoping that if they can bend with the wind, legislation will be avoided.

David Dickson

UK animal research

Legislation unlikely

British legislation on laboratory animals is hanging fire until the draft of a Council of Europe convention is agreed, supposedly in May. The government has said that new legislation will not be based on the amended version of the private member's bill first introduced into the House of Lords by Lord Halsbury last session and reintroduced this session. Members of the Lords committee that sat to amend that Halsbury bill now fear that further delays, due to tardiness in the Council of Europe or in drafting a new bill, could jeopardize agreement reached by opposing sides during the committee's deliberations.

The government hopes to avoid passing legislation clashing with the convention's aims. British legislation, however, is bound to be more stringent than the lowest common denominator between the Council's member states laid down in the convention. The latest available draft contains nothing that contradicts the Halsbury bill or that is likely to give the government's bill drafters pause.

Whether further amendments will cause problems remains to be seen. But the government's objections to the Halsbury bill are clearly on other grounds. During the second reading debate before Christmas, Lord Belstead for the government said that the bill leaves too much to the discretion of the Home Secretary and invests too many powers in an advisory committee that would be set up to review regularly ethical matters and the replacement and use of laboratory animals.

Lord Halsbury is far from content. He suspects that the main objections to his bill have come from Home Office inspectors who fear that an advisory committee, along the lines laid down in the bill, would disrupt their well-tried methods of working. Despite government assurances that the original timetable still stands, Halsbury fears that delays in the Council of Europe could push it back. He plans to keep the issue alive by pushing his amended bill through the committee and report stages in the Lords in May even though it is now clear that it will never get a reading in the Commons.

Judy Redfearn

Commonwealth meeting

Food for reserves

Dacca

Moves to bolster the dangerously low level of world food stocks were the main outcome of a meeting of Commonwealth ministers for agricultural and rural development held in Dacca, Bangladesh, on 11-13 February. The ministers agreed that by mid-1981 negotiations should be completed to create a new International Grains Arrangement aimed at providing some of the 500,000 tons of cereals needed annually to replenish the International Emergency Food Reserve.

This was the first full-scale Commonwealth ministerial meeting of its kind, and was attended by 21 of the 44 member countries. The Commonwealth is made up of 20 nations showing a food deficit, and 21 with a surplus in food production. The remaining 3 nations, including host-nation Bangladesh, are on the verge of becoming self-sufficient.

The ministers urged quick action from international funding agencies, especially the World Bank and the International Fund for Agricultural Development, which are concentrating on aid to the poorest countries. Extra resources were called for to enable the Commonwealth Fund for Technical Cooperation to give more aid to developing Commonwealth countries.

M. Kabir

Romanian agriculture

Research expansion

President Nicolae Ceausescu of Romania called last month for greater research effort in agricultural sciences. He was addressing the 11,000 delegates at the Second Congress of Workers in Agriculture, including experts on agriculture as well as workers from cooperatives, collectives and the small residual private agricultural sector.

Although, according to Angelo Miculescu, the Minister of Agriculture, agricultural production went up by 26.4 per cent during the 1976-80 Five Year

Plan, President Ceausescu had previously pointed out, at a working meeting on agriculture in January, that targets during the past five years had not been fulfilled, and that "resolute" measures would still be needed. Such measures, he has now told the congress, must include expansion of research on plant and animal genetics, soil quality and, for the economists, the logistics of a switch from the traditional farming structure of the countryside, to the development of agro-industrial complexes. The latter scheme, by which food-processing plants are located in the countryside, not only eliminates the need of transporting perishable foodstuffs to the cities for processing, but provides additional jobs to reduce the drift to the cities.

The new research priorities will be met from the present budget, apparently by switching funds from other sectors.

In all these changes, said President Ceausescu, the Academy of Agricultural Sciences in Bucharest must have an increased involvement both in planning and coordination. The Academy, and, indeed, the whole educational system, he continued, must train more agricultural specialists.

Higher education in the agricultural sciences, however, is not to be open to all. President Ceausescu says that only workers or former workers in agriculture may go to university to study agriculture. The practice by which a young city-dweller can go to an agricultural institute simply to qualify for a clerical job nominally connected with agriculture is to stop.

Similarly, agronomy centres where specialists are trained are to be reorganized. At present, future experts are trained at "picturesque" centres, whose sites are frequently chosen for reasons other than agricultural suitability. At one such centre near Bucharest, for example, experts are trained in handling tractors in hilly areas, although the centre itself is remarkably flat. The reason is simple, said the president. "Comrades from the Ministry of Agriculture" want the centre there, because it is a convenient place for them to go and make speeches.

Vera Rich

Romanian workers — due for some changes

CORRESPONDENCE

Genesis of genetics

SIR — I find the current interest among biologists in the findings of Górczynski and Steele^{1,2} somewhat surprising, since a report of Lamarckian inheritance was published about 3,000 years ago. It is written that:

"And Jacob took him rods of green poplar, and of the hazel and chestnut tree; and pilled white strakes in them, and made the white appear which was in the rods. And he set the rods which he had pilled before the flocks in the gutters in the watering troughs when the flocks came to drink, that they should conceive when they came to drink. And the flocks conceived before the rods, and brought forth cattle ringstraked, speckled, and spotted."³

Were these findings ever reproduced? If so, would it not be more appropriate to speak of Jacobinic genetics?

KIRSTEN FISCHER LINDAHL

Ethics of genes

SIR — It was with considerable surprise and no little confusion that I read Richard Dawkins' letter on genetic determination (*Nature* 12 February, p.528). In his commendable desire to dissociate himself from the National Front, he has left me totally perplexed about his actual views of the relation between genotype and phenotype. Near the end of his letter, he associates himself with the views of S.J. Gould, that the genetic basis of IQ is "trivially true, uninteresting, and unimportant". Yet earlier in the same letter, he says that genetics is sort of relevant since we may need to "fight all the harder" against genetic tendencies. But in his book *The Selfish Gene*, Dr Dawkins wrote that we are "robot vehicles blindly programmed to preserve the selfish molecules known as genes" (preface) and that these genes "swarm in huge colonies, safe inside gigantic lumbering robots, sealed off from the outside world . . . manipulating it by remote control. They are in you and me; they control us body and mind" (p.21).

It really is very vexing. Just as I had learned to accept myself as a genetic robot and, indeed, felt relieved that I was not responsible for my moral imperfections, Dr Dawkins tells me that, after all, I must try hard to be good and that I am not as manipulated as I thought. This is a problem I keep having in my attempt to understand human nature. Professor Wilson, in his book on sociobiology, assured me that neurobiology was going to provide me with "a genetically accurate and hence completely fair code of ethics" (p.575). I was

euphoric at the prospect that my moral dilemmas at last had a real prospect of resolution, when suddenly my hopes were dashed by an article in which Professor Wilson warned me against the naturalistic fallacy (*New York Times* 12 October, 1975). You can imagine my perplexity. I do wish I knew what to believe.

Perhaps I am just asking for that foolish consistency which Emerson tells us is the hobgoblin of small minds. But I see that Dr Dawkins himself is uncertain. I can only echo the question he asks in his letter. "Where on earth did the myth of the inevitability of genetic effects come from? Is it just a layman's fallacy, or are there influential professional biologists putting it about?"

Cancer causation

SIR — The Epstein-Swartz article which appeared in *Nature*¹ (and was essentially identical to the manuscript these authors presented at the autumn meetings of the American Public Health Association in Detroit) will elicit a variety of critical responses from those in the scientific community who are familiar with the specific aetiological links between cancer and the environment.

But here I would like to point out one major fallacy in the Epstein and Swartz piece — their premise (that lifestyle factors have been overstated in discussions of the aetiology of cancer) is based largely on the assumption that occupationally-induced cancers are more prevalent than previously thought. Epstein and Swartz criticize Dr Peto for dismissing "recent estimates of the importance of occupational carcinogens in a report by the US Public Health Service as exaggerated, unsound and unreasonable". This alleged "report" concluded that "as much as 20% or more" of cancers in the near term and future may reflect past exposure to specific carcinogens in the workplace.

Epstein and Swartz attempt to build up the credibility of this estimate by stating that the report was "prepared by nine named and internationally recognized experts in cancer epidemiology, statistics and carcinogens from three federal research agencies" and go on to add that "there is no basis whatsoever for recent unsubstantiated allegations by Peto and others that all or most of the authors of the government report have disowned or rejected it or its conclusions".

Epstein and Swartz are in error on two points in their discussion of occupational cancer and the so-called "estimates paper". First, nobody except those two authors and perhaps some regulators who wished to bolster their requests for more legal control over

occupational chemicals has ever cited the "20%" estimate in a serious, scientific context. Second, according to a detailed article by Ruth B. Schwartz in our publication *ACSH News and Views*² "7 of the 10 scientists responsible for these statistics believe they may be incorrect. Only one scientist defends them as reasonable". Two could not be reached for their opinions. Ms Schwartz's conclusions were based on her in-depth discussions with the various "contributors".

Perhaps the most succinct evaluation of the "estimates paper" on which Epstein and Swartz rely so heavily was made by Sir Richard Doll: "I regard it (the 'estimates paper') as scientific nonsense".

Badger debate

SIR — Dr Flowerdew's recent letter (*Nature* 26 February, p.742) makes me wonder what purpose the Mammal Society intended to serve by engaging in what can indeed now be called "the badger controversy". Dr Flowerdew says that the society spoke out because my report provided a "one-sided" interpretation of the evidence ("biased" in Dr Harris's letter of 11 December; *Nature*, p.532), and because my "categorical" conclusions and recommendations did not take sufficient account of "the complexity of the problem". But in Dr Harris's letter it was also said that the society was intervening because it was necessary to correct certain "factually misleading statements" that I had made. Yet neither letter adduces any new "fact". Those that they use are the ones which I had assembled. Nor did either correspondent spell out any "anomalies" in the story other than those which I had considered. Dr Flowerdew now says that there is no unequivocal evidence that the gassing policy will produce a long-term solution, by which I presume he means stamp out the disease. But no one has ever claimed that it would. Above all, the Mammal Society, on whose behalf Drs Flowerdew and Harris have written, does not propose any alternative policy which the Government could pursue in order to lower the level of the reservoir of the bovine tubercle bacillus in the affected areas of the South West — the existence of which, as Dr Plowright pointed out (*Nature* 1/8 January, p.8), they first denied, but which in Dr Flowerdew's present letter he, or the Mammal Society, now seems to accept.

I intended no "attack on the Mammal Society and some of its members" — Dr Flowerdew's words — when I asked on what scientific authority the society based its presumed criticisms. The authorities on whom

I myself relied were first, the many scientists and veterinary surgeons from the Ministry of Agriculture, Fisheries and Food whom I cross-examined during my enquiry; second, the three internationally-known students of animal disease whose help I acknowledged in my report — Sir William Henderson, FRCVS, FRS, Dr L. Goodwin, FRCP, FRS, and Dr W. Plowright, DVSc, FRCVS; and third, Professor T. McKeown, FRCP, well known for his studies of trends in tuberculosis and other diseases; the authorities in the Medical Research Council and Department of Health and Social Services who are concerned with tuberculosis; and Dr B.R. Cook, until recently with the New Zealand Ministry of Agriculture.

The officers of the Mammal Society may believe that their society is exempt from the usual convention that no scientific society has the licence to make corporate statements of a scientific nature on behalf of all its members. But if it is exempt, one is entitled to ask — indeed, one is in duty bound to ask, since we are talking about a matter of animal and public health that is of international concern — who were the authorities on whom the Mammal Society leant, and whose counsel was denied me. Dr Flowerdew bluntly declares that the officers of the society were responsible for the statements that have appeared over his and Dr Harris's name. But apart from Dr Frazer, not one of the officers listed by the society is shown as having either a medical or veterinary qualification, and while some of its members, in particular Dr Neal, are well-known badger naturalists, none has written — unless in some unquoted journal — either on TB in cattle or on disease in badgers. Indeed, apart from Dr Neal's writings, I can find only one paper on badgers by any officer of the society, and that is a note by J.F.D. Frazer on badgers in Kent. The society's publications appear in the *Mammal Review* and in the form of "notes" in the *Journal of Zoology*, published by the Zoological Society of London.

Four of some 120 papers that have appeared in the lifetime of the *Review* concern badgers, and only seven deal with pathological matters (mainly ectoparasites — none deals with TB or with diseases in badgers); while only 15 of 311 "notes" concern badgers, and not one TB. In the circumstances, I find it more than a little strange that Dr Flowerdew suggests, presumably on behalf of his society, that the Ministry of Agriculture, Fisheries and Food should establish a Scientific Advisory Group "containing a small number of independent scientists such as wild-life epidemiologists and statisticians" — he offers no names — to "analyse the data in detail" for the ministry's Consultative Panel on Badgers and Tuberculosis, with the unfortunate imputation that in the view of the Mammal Society the ministry's scientific and veterinary officers are incompetent, and that their analyses of the data they collect cannot be relied upon.

LORD ZUCKERMAN

University of East Anglia,
Norwich, UK

SIR — Why has the Mammal Society (*Nature* 26 February, p.742) not attempted a reasoned reply to the criticisms contained in the letters by Dr Plowright (*Nature* 1/8 January, p.8) and myself (*Nature* 22 January, p.218), and by Zuckerman in his further article (*Nature* 19 February, p.628)?

If it is now accepted that the use of gassing

by the ministry has substantially reduced herd breakdown in affected areas, its continuation is clearly indicated. There does not at present appear to be any other way of tackling this source of infection. Reduction of badger densities in affected areas not only reduces the chance of infecting cows because there are fewer badgers around, but offers the best hope of greatly reducing and possibly, as more is learnt, substantially eliminating tuberculosis from the badgers themselves. In this respect badgers are fortunate in that there is now no major external source of infection and the TB monitoring of dairy herds gives early warning of the presence of infected setts in a locality.

In their earlier letter the Mammal Society, while suggesting that "other more subtle factors may be significant", did not dispute that density might be of importance in the spread and maintenance of TB in the badgers. They have now gone back on this, stating that "there is no unequivocal evidence that TB in badgers is density-dependent". This statement is based on the maps of badger density and herd breakdowns included in the Zuckerman report (p.68,70) which, they say, show that "TB is not only prevalent in areas of high density, but also in areas such as South Dartmoor where the badger population is very low". Had they referred to the subsidiary reliability diagram relating to the badger density map they would have found that the cluster of infections in South Dartmoor falls in an area classified on the reliability diagram as "mainly guesswork". They have completely ignored Zuckerman's discussion in his article of the statistical laws governing the propagation of infectious diseases, and his deduction that the establishment and maintenance of TB among badgers in an area is likely to be strongly density dependent, from which it follows that, as a matter of long-term policy, badger population densities should not be allowed to become excessive, as they certainly appear to be in parts of the South West at present.

The reactions to our other criticisms are similarly irresponsible and misleading. They dismiss Dr Plowright's letter with the comment that it "presented no new information nor did he answer any of the points we raised". The main point of my letter was to cast doubt on the Mammal Society's suggestion that the apparent success of the gassing campaign might be due to the decline of TB throughout the country. They appear now to have partially, but not wholly, conceded this point. They make much of the large decline from 5.5 to 3.2 per cent of herd breakdowns in Cornwall from 1975 to 1976 "highlighted" by my graph, and claim that it could not have been wholly produced by the gassing campaign. That there was a marked rise all over the country in 1975, followed by a corresponding decline in 1976, was clearly shown by my graph, and was pointed out in my letter, but this does not preclude that a large part of the Cornish decline was due to the removal of infected badger groups, some of which may have been done by farmers without the cooperation of the ministry. In any case, if the Mammal Society wished to comment on the irregularities of the Cornish data they might better have directed attention to the disturbing rise of infection between January 1977 and September 1979 which, however, was matched by a substantial fall between October 1979 and March 1980.

There are two further glaring distortions of the evidence in their current letter. The first is

my "contention", for which I gave reasons, that the 15 per cent of Cornish herd breakdowns attributed to badgers in the report was clearly much too low. That this contention was indeed correct was substantiated by the further information that Lord Zuckerman gave in his article. The Mammal Society accept this, but by lumping together the figures for 1974–75 and 1976–78 they conceal the progressive reduction in the proportion of "unknowns" and were able to claim that "since 1974 badgers were still only believed responsible for a minority of breakdowns".

A similar concealment of the full evidence occurs in their comment on the origins of infection from specific badger setts. Zuckerman reported that he had been informed that for the whole of Cornwall 72 per cent of the 51 outbreaks definitely attributed to badgers were within 2 miles of infected setts and 33 per cent were within half a mile, and that for the West Penwith area the corresponding percentages were 97 and 47. All that they state is that for the whole of Cornwall 28 per cent (100 minus 72) were attributed to setts more than 2 miles away and that badgers rarely travel this distance in areas of high density. A glance at the herd breakdowns map (p.20) of the report shows that the West Penwith area, which covers the western tip of Cornwall, contains the major pocket of infection and was clearly the source of the majority of the herd breakdowns.

Finally, in connection with their long and almost unintelligible argument on the effects of the moratorium on gassing, may I make it clear that neither Zuckerman nor I ever argued that "TB in badgers and cattle immediately increased as a result of the moratorium"; we merely reported the latest available data. Obviously there are time lags. The full effects of the moratorium cannot be properly assessed until data for a further year are available. Also in this connection, what is one to make of the statement: "This . . . totally ignores the likelihood of natural cyclic trends in TB prevalence, as discussed in our original letter and the reply by Dr Yates"? There is no mention of cyclic trends either in their letter or in my reply!

FRANK YATES

Rothamsted Experimental Station,
Harpenden, UK

SIR — You have recently drawn attention to the controversy over the badger-gassing issue.

The Zuckerman report shows a rise and fall of tuberculosis in the South West and also in the rest of England from 1974 to 1980. Some factor, common to the South West and the rest of England, must therefore be sought. I believe that factor is one which the Zuckerman report carefully avoids — the resumption of health-certification of the Irish cattle imports in June 1976 after nearly two years of importing TB-infected cattle into the United Kingdom during the Irish veterinary inspectors' strike.

The reluctance of the Animal Health Authority to suspend Irish cattle imports at that time contrasts sharply with their present enthusiasm to destroy badgers on scant evidence.

NEWS AND VIEWS

Propagating rifts in seafloor spreading patterns

from Tanya Atwater

SPECIALISTS from diverse geological fields recently gathered together to discuss mutual studies in the Cascadia region of western North America. One of the highlights of the meeting was the showing of a computer simulation of propagating rifts in the Juan de Fuca region by Richard Hey of the Hawaii Institute of Geophysics. Ever since Vine and Wilson¹ applied their seafloor spreading description to the well mapped magnetic anomalies of this region, enthusiasts have been cutting and pasting coloured maps, trying to explain the oblique fractures and other complexities in the pattern. For several years Hey and his colleagues have been developing and refining the notion of propagating rifts^{2,3} to explain data collected along the relatively remote Galápagos spreading centre. When they applied the concept to the Juan de Fuca anomalies, the many complexities became easily understood and predictable.

Probably the most convincing evidence for seafloor spreading, continental drift and plate tectonics lies in the configuration of linear magnetic anomalies from the sea floor. Vine and Matthews⁴ and Vine⁵ showed these anomalies to be indicators of symmetrical additions of new material along mid-ocean ridges and Wilson⁶ and Vine and Wilson¹ showed that these anomalies are offset along transform faults and their fossil traces, fracture zones. The now classic pattern of anomalies and offsets is that shown in Fig. a. This pattern is constructed assuming that the transform

offset was inherited from the original shape of the spreading boundary and that it constitutes impenetrable end points for the two ridge segments which abut it.

The simple pattern of Fig. a is a useful model both for explaining the gross configurations of seafloor features and for determining world plate motions. For fine details, on the other hand, the pattern is an oversimplification. Anomaly profiles commonly show occasional local sections of extra or missing space compared with predicted symmetrical patterns. These perturbations have generally been attributed to small 'ridge jumps' at which time the centre of spreading suddenly shifted sideways to a new location, breaking a section off from one plate and adding it to the other. In interpretations of sparse magnetic profiles, the detected spreading centre jumps have generally been assumed to be instantaneous breaks across new ground. More dense surveys have shown this not to be the case, however. Rather, the new ridges appear to tear through the crust at rates comparable to spreading rates, 'propagating' forward from their tips and gradually overlapping and extinguishing the previously existing spreading centres.

The magnetic pattern created by such a propagating rift is most easily visualized in its stepwise form, as shown in Fig. b after Hey². At regular intervals, the lower right-hand rift propagates past the transform fault, taking over the spreading for a new length of ridge and establishing a new

transform fault at its tip.

The third figure, after Hey *et al.*³, shows the anomaly pattern formed by a continuous, slow propagation of the lower rift and continuous shifting of the connecting transform zone. The oblique V-shaped traces left in the anomaly pattern appear at first sight to be fault lines along which the anomalies were broken and offset after their formation. Hey² notes that, in fact, no fractures ever occurred in these directions. They are inherited patterns which he calls 'pseudofaults'. V-shaped patterns like these are very clear in the Juan de Fuca magnetic surveys⁷, in the Surveyor surveys further offshore⁸ and in the Galápagos surveys^{3,9}. In the Atlantic, magnetic anomalies are much less clear because of slow spreading rates, but V-shaped patterns have long been noted in the topography near the Reykjanes ridge¹⁰ and at mid latitudes¹¹.

Another phenomenon clearly related to the propagators is the occurrence of ferro basalts and related high-amplitude magnetic anomalies¹². These unusual basalts erupt primarily near the growing rift tips and may help us to understand the special environment in which these rifts occur.

The reason why one rift propagates to supercede another is not clear. It is common for the new rift to have a slightly different trend than the old, suggesting this is the mechanism by which spreading centres adjust to changes in stress directions. However, the propagation of

Marine magnetic anomaly patterns generated by seafloor spreading at: (a) A stable spreading-transform fault system¹; (b) An oblique rift propagating northwards in discrete steps²; and (c) An oblique rift propagating steadily northwards³. Oblique 'fractures' mapped at the Juan de Fuca and other spreading centres may actually be pseudofaults as shown in (c).

rifts can be seen to accomplish other interesting results, as well. In the Galápagos area, for instance, the rift has 'jumped' south several times (via propagating rifts), thereby maintaining a location near the Galápagos hot spot. Another suggestive relationship is that the propagators commonly migrate outwards from the proximity of hot spots³.

The examples of propagators thus far documented occur at transform faults of small offset. However, Hey *et al.*³ suggest that all rifts begin as propagating cracks. The present East Pacific Rise in the South Pacific seems to have slowly grown, gradually replacing one that lies, now extinct, to the east¹³. Similarly, the original rifting of the Atlantic may have been progressive as suggested by the non-isochronous edge of the magnetic quiet zone¹⁴. A more recent version of continental rifting can be seen in the Gulf of Aden and Gulf of Tadjourah where the rift appears to have propagated westwards

Tanya Atwater is Professor of Marine Geophysics at the University of California, Santa Barbara.

into the African continent at a rate of about 30 mm per year¹⁵.

The propagating rift idea is really only a small modification to our understanding of seafloor spreading. Yet, it is an extremely satisfying one since it explains so many diverse 'imperfections' in the record in such a simple way, and it gives us a much better insight into the processes by which rifts form and readjust to changing conditions. □

The detection of cellular transforming genes

from Peter W.J. Rigby

THE demonstration that the transforming genes of retroviruses are derived from cellular genes, designated proto-oncogenes¹⁻³, has considerable implications. If certain cellular genes are oncogenic when placed under the influence of viral control elements, perhaps other genes, or indeed the same ones, mediate chemical carcinogenesis by being expressed at high levels as the result of carcinogen-induced mutations. Recent work from the groups of Robert Weinberg (MIT) and Geoffrey Cooper (Harvard University) has shown that genes involved in chemical carcinogenesis can be detected by DNA-mediated gene transfer experiments.

Weinberg's group has been able to induce transformation by transfecting into non-transformed mouse fibroblast DNA from lines of mouse fibroblasts transformed *in vitro* by the chemical carcinogen 3-methylcholanthrene (MC)⁴. Efficient transfection occurs with only one such line, NIH3T3, the cells of which are presumed, for some reason, to be particularly efficient at taking up and expressing exogenous DNA. DNAs from fifteen transformed lines were tested and successful transfer of the transformed phenotype was obtained with DNA from five lines of MC-

transformed cells. High-molecular-weight DNA (~30 kilobases in length) was used and the efficiency observed was roughly 0.1 focus forming unit per µg of DNA (FFU µg⁻¹). Cell lines derived from the foci were subsequently shown to exhibit another parameter of transformation — the ability to grow in soft agar. Infection of the transformed cells with murine leukaemia virus failed to rescue a transforming virus, suggesting that transformation was not due to the activation of an endogenous retrovirus. The transformed phenotype could be passaged through a second round of transfection. Note that the DNA of the majority of cell lines tested could not transfer the transformed phenotype and, more important, neither could the DNA of some MC-transformed lines.

In a second report⁵, restriction endonuclease digestion of MC-transformed cell DNA was used to assess the number of transforming genes. A gene will be inactive in the transfection assay if an enzyme cuts within it whereas enzymes that cut outside the gene will have no effect. In each of four cases tested, *EcoRI* and *HindIII* abolished transformation whereas digestion with *BamI*, *XhoI* and *Sall* had no effect. It thus appears that the same gene is involved in transformation in each of the four cell lines. The transforming genes of other cell types, a rat neuroblastoma and a line of cells transformed by transfection with normal mouse DNA, exhibited

distinct patterns of restriction enzyme sensitivity. The lines showing the same pattern were all derived by *in vitro* transformation of mouse fibroblasts with MC. The DNA of many MC-transformed cells was not active in the transfection assay, so it seems likely that only a subset of MC-responsive sequences was being examined.

In this issue of *Nature* (p.261), Shih and his colleagues extend their observations by showing that the phenomenon is not confined to genes involved in the transformation of mouse fibroblasts. Cellular transforming genes can cross cell-type and species barriers — DNA from three out of four rat neuroblastomas induced by ethylnitrosourea transformed NIH3T3 cells as did DNA from a MC-induced mouse glioma. In each case the primary transfectants were tumorigenic and a second cycle of transfection could be demonstrated. Similar results were obtained with a variety of carcinomas, including the Lewis lung carcinoma of the mouse, a 7,12-dimethylbenzanthracene-induced mouse bladder epithelial carcinoma, a benzo-a-pyrene-induced rabbit bladder epithelial carcinoma and a human bladder epithelial carcinoma. The phenomenon was again not general, the DNAs of several neuroblastomas and carcinomas being inactive, and rescue experiments argued against the involvement of retroviruses. This paper provides direct evidence that mouse cells transformed by human carcinoma DNA have acquired human sequences. In DNA-mediated gene transfer experiments, cells generally seem to take up not only the gene that is being selected for (in this case the carcinoma transforming gene) but also any other DNA that happens to be in the calcium phosphate precipitate. Human DNA contains a repeated sequence family, known as the *Alu* family, that is not detectable in the mouse genome. Using a cloned *Alu* fragment as hybridization probe it was shown that the transformed mouse cells had also acquired many copies of the human *Alu* sequence.

Cooper's laboratory has reported similar results although there are important differences of detail⁶. Using DNA 30 kilobases or more in length (the same size as used by Weinberg's group), they obtained no transformation with DNA from MC-transformed cells of murine and avian origin or with DNA from corresponding normal cells. However, if the DNA was sheared to between 0.5 and 5 kilobases, transformation was obtained with both normal and transformed cell DNA. Cooper and his colleagues examined only one line of MC-transformed mouse cells so their failure to detect transformation with high-molecular-weight DNA does not conflict with the data from Weinberg's group, who found that only one-third of such lines scored positive in the transfection assay. The frequency at which Cooper's group observed transformation

Peter W.J. Rigby is a member of the Cancer Research Campaign Eukaryotic Molecular Genetics Research Group, Imperial College of Science and Technology, London.

with normal cell DNA, even after sonication, was extremely low and Shih and colleagues, observing such transformation, in fact at a higher frequency, regarded these data as of dubious significance. When Cooper *et al.* used DNA extracted from their primary transformants in a second cycle of transfection, they again observed transformation but at a much higher frequency (0.1–0.2 FFU μg^{-1}), comparable with that obtained by Shih *et al.* for the lines that they scored as positive. Cooper *et al.* have also performed virus rescue experiments which argue against a role for retroviruses and have used restriction enzyme digestion to show that there are at least two normal chicken cell genes capable of inducing transformation.

The following general picture emerges from these results. DNA from some chemically induced and spontaneous tumours will induce transformation even in high-molecular-weight form. In these cases the transforming gene is dominant and the genetic lesion causing transformation is likely to be *cis*-acting, for example an up mutation in the promoter controlling transcription of the gene. It is not possible to conclude that the gene detected is the primary target of the chemical carcinogen. In many other cases, however, the transformed phenotype is not transferable and the genetic lesion may therefore be *trans*-acting, for example a defect in a diffusible regulatory molecule. In these cases transformation may be induced if the DNA is sonicated to a small size before transfection. The model favoured by Cooper's group is that the sonication separates the transforming gene from regulatory sequences that normally control its expression. In the primary transfection, which is very inefficient, transformation occurs if the gene integrates close to a strong promoter. In a secondary transfection a high efficiency is obtained because the lesion is now *cis*-dominant.

This model depends on dosage. It says that genes which during normal expression are not deleterious, and may even be vital for normal growth and development, can be oncogenic when joined to regulatory elements which increase their expression. This model has received direct support from experiments by Vande Woude and his colleagues⁷. They have cloned a proto-oncogene, the murine cellular *src* gene, from normal mouse cells and shown that it does not transform when transfected into cells. If, however, the cellular *src* gene is joined to sequences from the 5' end of murine leukaemia virus which contain the strong viral promoter, the resulting recombinant DNA molecules transform efficiently.

Many questions remain. Clarification of the ability of normal cell DNA to transform and the effect of DNA size on transformation frequency is particularly important. While Weinberg's group have treated their data with great caution, they

are amenable to the interpretation favoured by Cooper and his co-workers, and one eagerly awaits the results of more detailed comparative studies. A second question is how many transforming genes are there and what is their relationship to the genes found in transforming retroviruses? The transfection assay should allow the detection of many transforming genes and Rapp and Todaro⁸ have published experiments suggesting that it will be possible to rescue genes capable of inducing a wide variety of tumours using retroviruses as vectors. The demonstration that the malignant phenotype of chemically transformed cells can be transferred by DNA transfection provides a ready assay which will allow the corresponding genes to be cloned. The availability in cloned form of genes

involved in chemical carcinogenesis will surely lead to enormous advances in our understanding of this process. Of critical importance is the demonstration that human transforming genes can be detected by transfection because the failure to isolate human transforming retroviruses has meant that we remain totally ignorant of the properties of the proto-oncogenes which are surely present in the human genome. □

Proline and protein procrastination

from Roger H. Pain

EVER SINCE it was realized that a polypeptide could not afford the time to explore all possible configurations before settling in the unique native conformation, the main thrust of work in the field of protein folding has been concerned with understanding how folding can take place so rapidly. The sequences of proteins are designed not only to ensure appropriate stability and biological function but also, and of equal importance, to direct the folding reaction along pathways which shortcut the majority of configurations and allow the native conformation to be reached in well under a minute. The broad outlines of how this happens are now fairly clear.

It is therefore strange, at first sight, to find that a mechanism currently the object of a substantial amount of effort is one whereby this highly sophisticated physico-chemical process is actually delayed by the molecular eccentricity of a few proline residues (see Freedman *Nature* 279, 756; 1979). The biphasic kinetics of refolding exhibited by many proteins have been explained by the general model

where U_S is an unfolded conformation which folds to the native state, N , with relatively slow kinetics because it has to undergo a prior rate-limiting change into the fast refolding form U_F . U_F contains prolines in the *cis* or *trans* isomers which

occur in the state N , but U_S is a form in which a proportion of non-native isomers have arisen by slow *cis-trans* isomerization. Thus, the kinetics of refolding are modified by a transformation which is itself almost spectroscopically invisible.

The evidence for this explanation is, in the words of Jullien and Baldwin (*J. molec. Biol.* 144; 1981), "strong but not yet complete". It has been supported by the key double-jump type of experiment. If state N is perturbed to state U_F by thermal, acid or solvent denaturation (jump 1), the kinetics of the refolding to N after removal of the perturbation (jump 2) will depend on the time allowed for the $U_S \leftrightarrow U_F$ equilibrium to become established. It is found that the slow phase becomes more pronounced the longer the time interval between the first and second jumps and that the activation energy is similar to that for proline isomerization. Furthermore, strong acid, which catalyses proline isomerization, also increases the rate of equilibration between U_F and U_S .

The above equilibrium is the simple model initially put forward in 1975 by Brandts, Halverson and Brennan (*Biochemistry* 14, 4953). However, it has always seemed intuitively possible that U_S could fold to a compact configuration, still containing the 'wrong' proline isomer, but then reorganize itself on subsequent isomerization to state N . Baldwin and his collaborators have shown that for ribonuclease this is true and, indeed, that the isomerization process can be speeded up in this folded state by as much as

Roger H. Pain is in the Department of Biochemistry at the University of Newcastle upon Tyne.

50-fold. The more general basic model for refolding is now

where I represents one, or a sequence, of intermediate states with improper prolines. Levitt has drawn attention to the consequence inherent in this model that the refolding route taken will be a function of the difference in conformational energy between the native state N and the similar though perturbed conformation containing the wrong proline isomer (*J. molec. Biol.* **144**; 1981). The higher the strain associated with the incorporation of incorrect proline isomers into the native conformation, the greater the relative importance of pathway (b) and the more the system will approximate to Brandts' original model. At the other extreme, if the difference in energy is low, pathway (a) will predominate and isomerization only be detectable insofar as the folded state I differs spectroscopically or in stability from state N. State I will be expected to be significantly populated under conditions favouring the 'native' state.

Levitt, on the basis of conformational enthalpy calculations, postulates three levels of strain energy resulting from the insertion of incorrect proline isomers, types I, II and III corresponding to energy differences of approximately 1, 10 and 30 kcal mol⁻¹. Types III and I correspond, respectively, to the two cases cited above, while in type II the folded state containing an incorrect proline would be relatively stable but significantly less so than the native state.

Jullien and Baldwin have taken up this classification and have suggested kinetic and environmental criteria whereby the three types may in principle be recognized experimentally. On the basis of spectroscopic and urea gel electrophoresis (Creighton *J. molec. Biol.* **137**, 61; 1980) investigations on about ten proteins, they find definite evidence for proteins with type II prolines only, although the existence of type I prolines cannot be ruled out. Thus, in any system some molecules refold fast, others slowly. Generalizations about globular proteins are notoriously prone to contradiction, however, and investigation of a wider range of proteins may reveal different behaviour.

Levitt's main contribution is to calculate the strain energies for each of the four prolines placed, as the incorrect isomer, in bovine pancreatic trypsin inhibitor (BPTI). The effect on the protein is shown to involve mainly local and relatively small shifts from the native conformation. He finds that the destabilization of the native

structure is 1 kcal mol⁻¹ for Pro 13 (therefore type I), 11 kcal mol⁻¹ for Pro 2 and Pro 9 (type II) and 33 kcal mol⁻¹ for Pro 8 (type III). On the basis of these assignments, one can calculate the proportion of BPTI molecules which will refold rapidly and Levitt obtains a value of 0.77. Jullien and Baldwin, who carry out a detailed experimental investigation of the refolding of a slightly modified BPTI, find that the relative amplitude of the fast folding $U_F \rightarrow N$ reaction is 75 per cent, in good agreement with the prediction. They also find one slow folding reaction which satisfies the criteria for a type II residue together with preliminary evidence strongly suggestive of one or two type I residues. Type III behaviour has not been found, although this may be due to greater conformational mobility in the modified BPTI which they study. The 'catalysis' of isomerization found experimentally has been studied by Levitt who calculates that states intermediate between *trans* and *cis*, with the peptide bond angle $\omega \sim 90^\circ$, have lower energies than the strain energies in

the *cis* form. The protein seems to be able to accelerate the rate of isomerization by applying a couple to the ω angle.

Taken together, these two different approaches provide more circumstantial evidence for proline isomerization as the explanation for the biphasic refolding of proteins. If the fast and slow phases do, in fact, correspond to the sequential $U_S \rightarrow I$ and $I \rightarrow N$ reactions where I is a compact configuration, and if most proteins turn out to fold as type II or type I, the proline quirk affects the exquisite efficiency of the folding process less than might have been initially feared. The polypeptide chain still collapses rapidly, as suggested by Creighton, to a compact form within which the prolines can sort themselves out at leisure. The collapse may be the most important feature in that it reduces the possibilities for entanglement between elements of different domains. Presumably the conformational requirements for proline residues in the folded protein outweigh the necessity for an overall rapid folding process. □

Defining a lectin

from Jan Kocourek and Václav Hořejší

Recent correspondence (see *Nature* **285**, 66; 1980) demonstrates that there is an urgent need to formulate a definition of lectins which clearly delineates the meaning of the term. However, Goldstein *et al.*'s proposed definition of a lectin as "a sugar-binding protein or glycoprotein of non-immune origin which agglutinates cells and/or precipitates glycoconjugates" seems to disregard some important points. In particular, because the role of lectins in living objects is unclear, it does not seem appropriate to define lectins by their *in vitro* biological activities. The agglutination of cells — a complex and poorly understood phenomenon — may, in the majority of cases, be a fortuitous effect of lectins. The definition of lectins should be based primarily on their most important physicochemical properties, that is, on their interaction with carbohydrates.

The inclusion into the definition of some *in vitro* activities of lectins, like agglutination of cells and precipitation of glycoconjugates, would exclude those lectins which have only one binding site and/or show some toxic or hormone-like activities. This is especially true in the case of the toxins of *Ricinus communis*

and *Abrus precatorius* which are structurally related to the 'agglutinins' and occur in the same sources so that their common evolutionary origin is obvious. Recent research shows that many of these agglutinins (including that of *R. communis*) may exert very similar properties to their toxic counterparts, if acting in cell-free systems (Barbieri *et al. Biochem. J.* **182**, 633; 1979).

As long as we consider lectins as recognition molecules and assume that they mediate information in various (but still largely unknown) physiological reactions, their definition should be based on only three distinct features which they all have in common. Lectins

- (1) have at least one binding site which can bind free or glycosidically linked carbohydrates: this interaction can be inhibited by low-molecular-weight sugars;
- (2) are not synthesized due to an immune response and do not have immunoglobulin structure;
- (3) do not show enzymatic activities towards carbohydrates to which they bind.

We thus suggest the following definition: lectins are sugar-binding proteins or glycoproteins of non-immune origin which are devoid of enzymatic activity towards sugars to which they bind and do not require free glycosidic hydroxyl groups on these sugars for their binding.

Chondritic meteorites: a changed and changing view

from R. T. Dodd

Two decades of intensive study of meteorites has drastically changed our view of their role in Solar System history. What R.A. Daly regarded in 1943 as fragments of a shattered tenth planet¹, we now recognize as samples of at least 20 (ref. 2) and perhaps more than 70 parent bodies³, most or all of which were no larger than Ceres, the largest modern asteroid (with a radius of 385 km)^{2,4}. Some of the meteorite parent bodies experienced partial melting and fractional crystallization to yield the diverse rocks that we know as iron, stony-iron and achondritic stony meteorites. Others escaped such differentiation and yield samples of rocks — chondritic meteorites — that formed during or very shortly after condensation of the solar nebula and underwent little physical and less chemical alteration thereafter. While the differentiated meteorites provide valuable insights into planetary evolution⁵, chondrites contain a unique record of the earliest stages in Solar System history, and some of them contain isotopically bizarre materials that may predate formation of the solar nebula and/or come from beyond it⁶. All meteorites are important, but the chondrites alone among accessible materials are survivors of the first steps in the 4.55 Gyr progression from interstellar gas to modern man.

Chondrites are more or less recrystallized agglomerate rocks (see the figure) whose bulk chemical compositions (ignoring H, He and other gases) resemble the composition of the Sun. Though all chondrites are, in this sense, chemically primitive, they show discontinuous variations of oxidation state and ratios of major non-volatile elements that divide them into three chemical classes and at least eight smaller chemical groups (see the table). There is general agreement that these variations reflect processing of chondritic material before or during its accumulation in at least eight parent bodies, though the nature of that processing remains unclear^{4,7,8}. There is also a consensus that the recrystallization evident in most ordinary and enstatite and some carbonaceous chondrites signifies the thermal metamorphism in^{4,9} or on^{8,10,11} the

surfaces of the parent bodies; the specific mechanism is again unclear⁴.

Much discussion of chondrites centres on the origin of chondrules, the millimetre-sized, drop-formed or irregular bits of rock from which these meteorites take their name (see the figure). Chondrules are present in most carbonaceous and all enstatite and ordinary chondrites, and their origin is highly controversial. Of the

Photomicrograph, in transmitted light, of the Manych ordinary chondrite. Chondrules, which comprise almost 90 per cent by volume of this meteorite, consist chiefly of olivine, pyroxenes and residual glass. The field of view is 16 mm wide.

many processes invoked to explain them — condensation of droplets from nebular gas, fusion of nebular dust by various means, shock melting of dust or rock on parent body surfaces, explosive volcanism and metamorphism — only the last two have no modern proponents, and only the last is clearly inconsistent with the properties of chondrules.

Debate over the origin of chondrules remains spirited, but new analytical methods (electron microprobe, neutron activation and isotope dilution analysis) have provided analyses of individual chondrules that place tight constraints on models. Chemical trends among chondrules in carbonaceous chondrites strongly suggest that these objects, like the refractory inclusions in such meteorites, formed in the condensing solar nebula, by condensation of droplets and/or fusion of solid condensates¹². On the other hand, chemical variations among chondrules in

ordinary chondrites suggest that they post-date condensation and formed through shock melting associated with the growth of parent bodies¹³. It thus appears necessary to appeal to different processes and/or times of formation⁴ to explain chondrules in carbonaceous and ordinary chondrites.

Chondrules in enstatite chondrites have received little attention to date, largely because of the perception that all such meteorites are metamorphic rocks¹⁴. Two recent papers on such chondrules^{15,16} are therefore welcome. They suggest that metamorphism is a less severe problem than believed, and that the chondrules in enstatite chondrites are remarkably complex objects that may require yet another explanation.

Leitch and Smith showed that chondrules in the Indarch chondrite contain two types of clinopyroxene (essentially MgSiO_3)¹⁵ and two types of olivine (essentially Mg_2SiO_4)¹⁶ that differ in minor element contents and cathodoluminescence colour. That these and similar phases in the Kota-Kota chondrite¹⁶ occur together but do not intergrade makes it unlikely that either meteorite experienced significant metamorphic alteration. In the standard classification of chondrites by composition and degree of recrystallization¹⁴, they probably belong to type E3 rather than E4.

Leitch and Smith (ref. 15 and see this issue of *Nature* p.228) observed that the distribution of the two pyroxenes and two olivines is very complex — some chondrules contain all four minerals — and hard to reconcile with a direct connection between chondrule formation and nebular condensation. They suggest that enstatite chondrites bring together materials from at least two nebular sources, whose history included condensation, formation of planetesimals, collisional destruction of these objects and accumulation of the resulting debris.

Many aspects of this scenario need further study, as its authors admit. It is important, for example, to characterize the fine material between crystals in chondrules, which Leitch and Smith assume to be dust and vapour deposits. This writer is also troubled by their explanation of droplet chondrules, which tend to contain either red- or blue-luminescing pyroxene (or orange or blue olivine) and are thought to sample different planetesimals. It is not clear why liquids generated by collisions should sample only one of the colliding objects.

R. T. Dodd is Professor of Mineralogy in the Department of Earth and Space Sciences, State University of New York at Stony Brook.

Abundances and chemical properties of chondrite classes

Class	Groups	Falls	Fe/Si	Atomic Fe ^o /Fe	Mg/Si
Carbonaceous	>4	33	1.6–1.8	0.0–0.1	0.90–0.92
Ordinary	3	314	1.2–1.6	<0.1–0.6	0.80–0.83
Enstatite	>1	11	1.1–2.0	0.7–0.8	0.63–0.68

Abundance data from ref. 8; approximate ranges of ratios from ref. 4.

The Leitch-Smith model for chondrule formation is at present skeletal, but their demonstration that essentially pristine enstatite chondrites exist is very important. It encourages those (for example ref. 16) who are attempting to study chemical variations among chondrules in these meteorites. It should also encourage other workers to move into this neglected corner of chondrite research.

Evidence that the chondrules in carbonaceous, ordinary and enstatite chondrites tell quite different stories illustrates very well the marked change in view alluded to at the beginning of this article. Daly¹ interpreted chondrites as samples of a planetary mantle and thus, by implication, chemically and physically differentiated materials. Had he proved to be correct, we might now know more than we do about the interior of our planet, but we would surely know much less about its origin. A shattered tenth planet is emotionally appealing, but it would tell us much less about the Solar System's history than 20 or

more smaller objects caught at various stages of internal evolution. That the meteorite parent bodies were numerous and varied might disappoint Daly, but it is very good news for planetary scientists. □

Why is the moon slowing down?

from David W. Hughes

THE Moon orbits the Earth every month and on average moves 13.2° per day across the sky. As long ago as 1695 Edmond Halley (*Phil. trans. R. Soc.* **19**, 1690; 1695) suspected that the Moon was slowing down in its orbit. Now, that the effect has been confirmed, two main causes have been proposed: tidal dissipation and variation in the value of G , the universal 'constant' of gravitation. Measurements of this acceleration have been reviewed and interpreted by F.R. Stephenson of the Department of Geophysics, Liverpool University in a recent edition of the *Journal of the British Astronomical Association* (**91**, 136; 1981).

Tidal friction retards the Earth's rotation. The length of the day is thus slowly increasing at a rate of about one second in 50,000 years. As an autonomous system conserves its angular momentum, the angular momentum lost by the Earth is gained by the Sun and Moon. The Sun is so massive that the reciprocal effect on it is negligible but the Moon does, however, gain a significant amount of angular momentum at the expense of the Earth. This causes our satellite to drift away at a rate of about 4 cm per year.

The acceleration of the Moon can be calculated in two independent ways. The first relies on the analysis of ancient eclipse

observations which extend back over 2,000 years. The difference between the predicted lunar position, if we neglect acceleration, and the observed position which obviously is affected by the acceleration, increases as the square of the elapsed time. Over 2,000 years this difference is as large as two or three degrees. The most recent result obtained using this technique is -30 ± 3 arc sec century⁻². An indirect method based on the observations of the transits of Mercury since 1743 produced a result of -26 ± 2 arc sec century⁻².

The second approach is through the study of oceanic tides. Recent research has shown that the sea level has not varied by more than a few metres over the last three millennia and there is no evidence of any significant change in the lunar tidal friction over the past 2,500 years. It has also been found that the vast open oceans are the major energy sink and not, as previously thought, shallow regions such as the Bering Sea. Calculations of the mean rate of work done by the Moon on the ocean surfaces resulted in an acceleration of -30.6 ± 3.1 arc sec century⁻². Ocean tides perturb the orbits of Earth satellites and an analysis of these perturbations lead to a result of -27.4 ± 3 arc sec century⁻².

The recession rate $\dot{r}$ is related to the accel-

eration $\ddot{r}$ and the rate of change of the constant of gravitation $\dot{G}$ by the following equation:

$$\frac{\dot{r}}{r} = -\frac{2\ddot{r}}{3\dot{r}} + \frac{1}{3} \frac{\dot{G}}{G}$$

If $\ddot{r}$ is measured and $\dot{G}$ is assumed to be zero, $\dot{r}$ can be easily calculated. The present value for $\dot{r}$ is 4.0 ± 0.3 cm yr⁻¹. The Moon was once much closer to the Earth than it is now. G.H. Darwin (*Scientific Papers* **2**, 208, Cambridge, 1908) originally extended this deduction to claim that the Moon may have originated as part of the Earth. The recession rate is inversely proportional to the sixth power of the distance. The assumption that the present rate of energy dissipation has always been active would bring the Moon catastrophically close to Earth less than 1.5×10^9 yr ago. The Earth is three times older than this. Here, to quote W.H. Munk (*Quarterly Journal of the Royal Astronomical Society* **9**, 352; 1968), "we are extrapolating from a few thousand years to a few thousand million years, always a dangerous undertaking, and a harrowing one when the very process is in doubt". Fortunately it has been shown that even moderate changes in the shape of oceans and adjacent seas may materially affect the tidal dissipation and hence the recession rate. The astronomical approach thus seems to be of little help in solving the problem of exactly where the Moon was in the geological past.

The difference between the acceleration measured as a function of Ephemeris Time and the acceleration measured as a function of Atomic Time yields the non-tidal component and consequently the rate of change of G . Some 7,000 observations of lunar occultations of stars have been used by Van Flandern to find an Atomic Time value of the acceleration of -36 ± 5 arc sec century⁻². Laser reflectors have been also placed on the Moon by Apollo astronauts and have been used to give a lunar acceleration with an Atomic Time value of -23.8 ± 4 arc sec century⁻².

Stephenson carefully combines the Ephemeris Time and Atomic Time values of the acceleration. There seems to be considerable overlap between the two data sets and he concludes that the present observational evidence is quite consistent with the interpretation that $\dot{G}$ is zero and the universal constant of gravitation is not varying.

What will be the end result of lunar recession? The day (the Earth's spin period) and the month (the lunar orbital period) are both increasing, the day faster than the month. Eventually it will take Earth fifty-five of our present days to spin once. It will also take the Moon fifty-five days to orbit. Day and month will be equal and the same part of the Earth's surface will always face the Moon. □

Intergenic conversion and reiterated genes

from Richard Egel

GENE conversion between reiterated genes is currently gaining recognition as a novel means for exchange in the genome. The term gene conversion stands for the replacement of a particular DNA sequence by a different one. This process is usually initiated by the formation of hybrid DNA between two partially complementary single strands. In general, they belong to two double-stranded molecules. The following discussion, however, deals particularly with the special case when both originate from slightly different parts of the same chromosome.

Until recently, gene conversion has been the esoteric refuge of a few fungal-geneticists who studied the hidden secrets of recombination from aberrant tetrad configurations, joined only by a few determined drosophilists who examined 'half tetrads' of 'attached X' chromosomes, in which the two homologues are connected by a common centromere. These studies suggest that heteroduplex or hybrid DNA is a local intermediate in recombination events of any sort. In a single meiosis, any pair of allelic markers should segregate 2:2 unless they are drawn into a recombination event, in which case various deviations from the regular 2:2 distribution may and do occur. In fungi with four spores per tetrad, 3:1 events are the easiest to detect. In other fungi with eight spores per tetrad, 6:2 and 5:3 events were the first aberrant classes analysed. Originally, such a skewed segregation pattern, where one of the markers had fallen into minority, was classified as 'gene conversion', but it is now common practice to call the formation of hybrid DNA a conversion event, irrespective of whether the final segregation pattern becomes skewed or remains symmetrical.

To understand recombination, one must focus on a single intermediate — the piece of hybrid DNA where two single strands from different molecules have reannealed (Fig. 1). In general, such a reannealing will not lead to a perfect match as any difference in base sequence will reveal itself as a misalignment, comprising single bases or larger loops of noncomplementarity (a). Such discontinuities are either left alone until they are resolved by replication (b), or are erased before replication by repair synthesis (c), using one or the other strand as the conserved template.

If one now considers the adjoining stretches of homoduplex DNA on either side of the hybrid, there are two basic possibilities (Fig. 2): the flanking sequences can originate from the same molecule (a), or they may come from the two molecules that contributed to the

Richard Egel is a professor at the Institute of Genetics, University of Copenhagen.

Hybrid DNA as an intermediate in recombination

Fig. 1 A stretch of hybrid DNA (a), including a noncomplementary region, can be replicated directly (b) or first corrected by repair synthesis (c).

Fig. 2 The hybrid region can be part of a continuous molecule (a) or recombine two different ones (b).

Fig. 3 The 'Aviromore model' of hybrid DNA formation between two molecules¹. Newly synthesized DNA; ———— degraded strand.

hybrid (b). In the first case a limited piece of single-stranded DNA has invaded another duplex without disrupting the overall arrangement of that molecule. In the second, the outer parts have assumed a recombinant configuration.

Usually both the DNA molecules engaging in recombination come off intact. This conservation can be accounted for by the following dynamic model¹, which also takes care of other observations (Fig. 3). At special sites, one of the strands is opened (O), and one of the single-stranded ends begins to invade the partner molecule. The leaving strand is peeled off further, and the gap in its wake is filled by DNA synthesis, using the remaining strand as a template. It may, in fact, be this synthesis that actually drives the reaction. In the receptor molecule, the strand displaced by the invader seems to be degraded initially, but at any moment (S), it can likewise start to invade the partner molecule, whereafter the further formation of hybrid DNA will be symmetrical. This two-phase scenario with a switch from asymmetrical to symmetrical formation of hybrid DNA has been verified experimentally in the fungus *Ascobolus*^{2,3}.

At the final stage (H), the connected molecules are known as the 'Holliday structure' or a 'half chiasma'. The junction is relatively free to move back and forth by the concerted rotation of the four double-stranded arms. Eventually, however, this connected structure needs to be resolved. In meiosis, where recombination is generally thought to occur between two of the four chromatids available after replication, the Holliday structure must be

broken by the cutting of two equivalent strands — the two 'inner' ones or the two 'outer' ones, as placed in the drawing (H). These two alternatives may well assume a less asymmetrical configuration when viewed in three dimensions. In mitotic recombination, however, when hybrid DNA appears to be formed at the two-chromatid stage, resolution is more likely to result from replication through the Holliday structure⁴, rather than by strand cleavage before replication.

A priori, there is no reason why the recombination processes outlined above cannot occur within families of reiterated genes, such as the rRNA, globin or antibody genes. Hybrid DNA can still be formed as long as there is sufficient sequence homology. As the flanking regions may not be homologous, however, their rearrangement by crossing-over will not, in general, be tolerated as this might lead to a change in the arrangement of genes. However, the invading strand can also be disconnected from its source, so there could be recombination between the reiterated coding sequences alone. In this way the overall arrangement of the receptor chromatid would remain the same. This type of information transfer between related but different loci has recently been documented in various organisms.

That recombination essentially depends on local DNA homology is widely accepted. For example, when the *rosy* gene of *Drosophila* is placed inside a heterozygous inversion, the frequency of gene conversion is not changed⁵, whereas crossing-over in the inverted region is

deleterious, generating a dicentric chromosome together with an acentric fragment.

Duplicated genes are often located in a tandem arrangement. This situation can now be simulated experimentally by gene-cloning techniques. Klein and Petes⁶ selected a yeast transformant, in which the wild-type *leu2*⁺ gene, together with a bacterial vector, was integrated in the vicinity of the chromosomal *leu2* gene, which was marked by two frameshift mutations. This strain was then crossed with a *leu2*⁺ partner. Hence, one of the chromosomes of the diploid carried two *leu2* genes in tandem, only separated by the vector DNA. In the absence of recombination, all four spores of a tetrad should receive a copy of the *leu2*⁺ allele and grow without leucine. Occasionally, however, tetrads were observed in which one spore was auxotrophic, due to one or both of the original frameshift mutations. When these aberrant tetrads (12 of 306) were analysed further, the largest fraction (6) was due to conversion between the duplicated genes. Four cases were due to conversion between non-sister chromatids, and only one was due to crossing-over. One tetrad was apparently caused by a multiple event, but it could also be explained by early conversion, if hybrid DNA was formed before the premeiotic S phase — similar to what is usually observed for mitotic recombination. On the basis of these results, the authors conclude that the cells can use gene conversion to maintain sequence homogeneity in a family of reiterated genes. For this purpose, conversion is more efficient than crossing-over at staggered places in a tandem series, the rectification mechanism previously proposed⁷ because with conversion the overall number of genes will be maintained.

Circumstantial evidence for the occurrence of similar events outside the laboratory has recently been detected in the DNA sequences of three human globin genes⁸, two of which were reiterated on the same chromosome with the third allelic to one of the others. As is usual for globin genes, the expressed parts of these genes are interrupted by several introns, and it is one of these that apparently has been subject to intergenic conversion. This conclusion was based on the observation that two equivalent introns of the reiterated genes contained a segment more similar to each other than to the allelic counterpart. Interestingly, this segment was located adjacent to a presumptive hot spot of recombination.

Working with quite a different system, Munz and Leupold⁹ reported genetic evidence for the specific exchange of information between reiterated tRNA genes in fission yeast. They studied the reappearance of suppressor-active alleles that had been inactivated by secondary mutations. This exchange was also most easily interpreted as intergenic conversion.

Intergenic conversion has also been

applied to an analogous phenomenon — mating-type switching in homothallic yeast strains¹⁰⁻¹². It appears that a certain piece of DNA is transferred from a silent position to an expressible site, where it replaces the piece of information previously residing there. This switches the functional mating type to the opposite type. The information transfer is highly asymmetrical in the sense that the source segment is usually left unaffected, and the target segment to be displaced usually discarded. The organism has thus adopted a conversion mechanism for the purpose of gene control, and it has done so by channelling the course into a unique direction.

What other systems are likely to benefit from similar explanations? Gene conversion may perhaps play a role in the generation of antibody diversity. Reciprocal recombination can apparently explain a host of data from V-C joining to class switches. However, the experts still appear divided over whether hypervariable regions can recombine as mini-genes¹³. Their independent incorporation into the framework of the V genes would certainly increase considerably the combinatorial

possibilities. This idea, alas, was badly hit by the discovery of a full set of hypervariable regions in the first V gene from the germ line to be sequenced. However, that blow need not be as fatal as it seems, because only the downright insertion of new sequences is immediately excluded, and not the substitution of one sequence for another of equivalent length. That is precisely what conversion has to offer. So there is still room for mini-genes to jump about, and the search for more evidence need not be called off just yet. □

100 years ago

In a paper "presented to both Houses of Parliament" the subject of "*oleomargarine*" as manufactured in the United States is discussed. This substance is made from beef suet by disintegrating in warm water, passing through a fine sieve, melting at 120° F., settling, draining off the oil, and allowing to solidify. During the year ending June 1880, 18,833,330 lbs. of oleomargarine were exported from New York, the greater part going to Holland. The manufacture and sale of this substance is strongly condemned by many butter merchants, and as strongly recommended by various well-known American chemists. Analyses given in the report show very small differences between oleomargarine and natural butter, except in the particular of soluble fats, of which oleomargarine contains considerably less than natural butter.

Cave Animals and Multiple Centres of Species

The readers of Semper's "*Existenzbedingungen der Thiere*," now translated into English, will find (vol.ii, p.268 of the German edition) an interesting discussion of the question of monophyletic or polyphyletic evolution of species, the author decidedly inclining to the latter hypothesis. Considering that at the root of the manifold and difficult problems here involved, there is the relatively simple one of single or multiple centres of each species in a biographical sense, I take leave to ask the following question, hoping for an

answer from among your readers versed in these matters.

To me it seem impossible to maintain the single centres of species in a strict and definite sense without also maintaining the single progenitor of each species, which latter view, formerly considered as a necessary assumption, has been given up by Mr. Darwin in Chapter IV. of the later editions of "*Origin of Species*" (5th ed. p.103, 104). Of course the acceptance of single centres, in the sense of more or less restricted areas of origination, may remain valid for the vast majority of species.

Now, I have sometimes thought that there might be a test for the possibility of multiple centres, which, eventually, would amount almost to an experimental demonstration — namely: *whether there are cases of the same species of blind animals occurring in different caves distant from and without subterranean communication with each other?* Should such cases occur it would be most improbable that the animals in question had been transported from one cave to the other in the modified state, and most probable that they had been independently evolved in each cave from identical species which entered it from without. I formerly noted one instance perhaps in point, viz. a statement of Prof. Cope's (*Nature*, vol.vii, p.11) that "the blind fish of the Wyandotte Cave is the same as that of the Mammoth, the *Amblyopsis speclaeus*, Dekay," but I am not aware whether subterranean communication is, or has been, impossible in this instance. Perhaps more decisive cases have become known of late?

COMPUTERS IN THE NEW LABORATORY

Where will the revolution end?

Computers have come to stay. And the uses of computing machinery are by no means confined to the first and more obvious applications, the solution of problems in large-scale arithmetic. The pages that follow are intended to point to some of the more conspicuous ways in which computing machinery is being used for the solution of problems in scientific research which are not mere computation. What follows is not, however, a survey of this now vast field but rather a pointer to some of the trends that have become apparent in the past few years. There is every prospect that, in the years ahead, the scientific uses of computing machinery will grow still further. Where will it all end? And what will be the consequences for the practice of scientific research?

One of the most conspicuous developments in the past few years has been the use of computing machinery in the handling of data, but the passage of time serves only to emphasize how much remains to be done. In many circumstances, there is no alternative to computerized handling. It is unthinkable that the data collected by, say, the Einstein X-ray satellite could be handled in any other way. The same is true of the vast amounts of data collected by detection equipment in high-energy physics, some of which yield information in a thousand or so parallel channels in intervals of time no greater than a microsecond. In these respects, computers have literally made possible some kinds of experiments. But data-handling techniques also enhance the value of data. The Einstein satellite is again a striking illustration of what can be done (see page 197). If the detectors (by their nature) record the time at which X-ray photons arrive, or their energy, why not design the data-handling system to exploit this extra information? In this respect, computers can wring more out of an experiment, or a series of observations, than is possible with more traditional techniques of data handling. It is natural that astronomers of all kinds should be alive to the possibilities with which they are now presented. Others will no doubt follow suit.

Another of the important trends of the past few years (hardly referred to in what follows) is the use of computing machinery for simulation. Some of the most ambitious essays of this kind are the climatic models that have been developed at half a dozen centres around the world. The objective is to represent within the circuitry of a computer the physical processes occurring in the real atmosphere. Climatic models are notorious in their demands of the computer hardware, while the development of climatic programs is hampered not only by the complexity of the problems but by ignorance of, or at least uncertainty about, some aspects of the underlying processes. Even so, climatic models have brought valuable understanding to some important aspects of the problem of climatic change. They have surprisingly been less effective at the identification of the physical problems that must be better understood before reliable models can be designed.

Already there have been some striking and successful applications of simulation in the study of the nervous system for example. In other fields, however, simulation by computer model has lived up fully to its purpose, to demonstrate the validity of a theory or to identify its weak points, and to serve as a convenient and rapid means of telling what will happen in the real world. This is another persistent trend.

Computers that run experimental equipment are also on the march. Again, it is unthinkable that the instruments carried aloft by rockets and satellites could be operated differently, but the sophistication of the technology now in use is a quite remarkable demonstration of what has been accomplished in the past twenty

years, partly no doubt because of military interest in the same techniques. That experimental equipment in, for example, high-energy physics should be controlled in the same way is also easily understood — there is no choice. With the introduction of relatively cheap microprocessing equipment, however, other surprising applications of this kind have come to light. In some quite small laboratories, it turns out to be worthwhile to use such a piece of machinery for controlling a piece of standard equipment from which a sequence of observations is required. The benefits are certainty, speed and the saving of research assistants' time. The cost is often small.

In the nature of things, however, most excitement in the years ahead will lie in directions not now foreseen. To many people, the use of computers for carrying out routine algebraic calculations (see page 198) will be a surprise. With hindsight, of course, this development seems natural enough. But how many would have staked money or reputation on the feasibility and the success of this development ten years ago, when computer algebra was in its infancy? And who now can guess what other developments, perhaps more radical, are buried in embryonic form in the research programmes of the computer laboratories?

Many of the applications of computers in past decade have made possible tasks that otherwise could not (or would not) have been attempted. Most of the same applications have been conceived of by the people most concerned to benefit from them — researchers themselves, not the manufacturers of computer hardware. And the chances are that the burden of innovation will continue to fall on the ultimate beneficiaries. With this in prospect, there would seem to be an urgent need that researchers in all fields, not simply those in the physical sciences, should be equipped by their education to be able to appreciate the possible benefit of computer applications. Although, as the experience of recent decades suggests, the most unlikely disciplines appear to accrete their own bands of computer enthusiasts, it seems unwise that they should rely on such a random process. The implications for the education of graduate students are obvious. Some practical experience of how to put a computer to good use is essential. But it may be even more important that graduate students should be led to understand the limitations of computer machinery — and to appreciate the pitfalls of over-dependence.

Like all blessings, the new computer technology is, after all, a mixed blessing. Making computers work well can rarely (outside the computer laboratories) be an end in itself. And the pace of discovery would be constrained if too many working scientists spent too much time writing programs for machines. It may also be damaged if the seductiveness of computing machinery, and the temptation to ask too much from simple computer programs, leads laboratories into spending too great a proportion of their resources on what is, after all, merely a means to an end. □

Computers and the biologist

Among biologists, physiologists have inevitably taken most readily to the use of computers; people brought up to know the difference between d.c. and a.c. amplifiers are naturally more inclined to give house-room in their laboratories to further electronic equipment. Yet the past few years have seen the infiltration by computers of most other kinds of research laboratories.

In all kinds of laboratories, the chief use of computers is still in the storage and analysis of data. The principles are as old as computers themselves. Data are digitized, stored within the accessible part of the computer or dumped onto magnetic tape, and analysed by whatever computer program is appropriate. In the 1960s, most large biological laboratories found it expedient to install substantial main-frame computers to provide their members with a data-processing service. Now, however, with the arrival of mini-computers and microprocessors, the trend is towards distributed computer capacity. Individual laboratories are acquiring their own mini-computers, while many pieces of equipment are now designed to operate with their own built-in microprocessors. (Most manufacturers of substantial pieces of equipment, for radioimmunoassay, for example, now provide floppy disks which allow the users to play games such as *Star Wars* as well as the more sober programs required to analyse the data, no doubt from compassion for those working in laboratories with time on their hands.)

This trend is probably inevitable, and unstoppable. For the user, the obvious advantage is to be fully independent, able to process one's data whenever necessary. Central machinery working on a batch-processing basis is necessarily by comparison an encumbrance. And there has grown up a certain air of disenchantment, at least among biologists and biochemists, with computer systems designed to be accessible by means of computer terminals in the laboratory.

Nevertheless, some of those concerned with the provision of computing facilities in general purpose laboratories are uneasy. Although the new small computers and microprocessors are cheap, the software required for specific specialized function may make serious demands of program-

ming skills. The end result, some gloomy calculations suggest, may be that the central cost to laboratories may be greater than at present. The alternative, that individual researchers should themselves become skilled at programming their own machines, is regarded with apprehension.

Laboratory administrators are also uneasy about the cost of measuring equipment with built-in microprocessors. The convenience and efficiency of these machines is beyond dispute. The suspicion is merely that the value added by the manufacturers of the equipment may not give the user a fair share in the cost benefits of the cheaper hardware now available.

The truth is probably that laboratory administrators are learning a painful lesson in economics. The development cost of software for a commercial measuring instrument is likely to be greater than that of writing a program in a particular laboratory. But the manufacturers of the measuring instruments with built-in microprocessors also find that demand is buoyant, suggesting that people able to afford the new equipment are prepared to pay for its convenience.

There are several well-attested illustrations of the costs that can be saved by home-made equipment. Thus one West Coast neurophysiologist, unable to afford from his current grant the \$20,000 to buy a suitable wave-form analyser, reckons that he was able to produce a better system for a quarter of the cost and at the same time produce a system of analysis better suited to his needs. The underlying dilemma is familiar — to what extent should research laboratories spend their time and energy on the construction of instruments which are nevertheless obtainable commercially.

Not all of the tasks of the general biological laboratory have as yet been delegated to the instrument manufacturers, however. Indeed, even in some of the most familiar tasks, the analysis of electrical output from physiological preparations for example, formidable intellectual difficulties keep cropping up.

The standard record in such experiments consists of a voltage (or several voltages) varying with time, on a time scale of milliseconds or thereabouts. Given a visual trace of such a voltage, it is possible with a ruler to estimate parameters such as the peak voltage, the time taken to reach that voltage and so on. Computer systems store the same information in digital form, and there are constant (if groundless) worries about the extent to which such data embodies "everything". More seriously, physiologists are likely to insist that some form of visual record should be obtained in parallel with whatever computerized analysis is found convenient. Machines may be able to analyse complicated sets of data once they have been provided with criteria for setting about this task, but

cannot recognize novel kinds of patterns.

So much is evident in the difficulties which keep cropping up in the research programmes intended to provide more sophisticated monitoring of the physiological condition of hospital patients, people in intensive care units for example. Many of the systems developed for this purpose depend on the recognition of abnormal trends in, for example, heart-beat rate, or variation from one cycle to another. One difficulty is that too little is known about the statistical properties of normal heart-beats to provide a sure yardstick for abnormality. The result is that false warnings abound, while few are confident that the systems now in use are capable of recognizing more than a small proportion of impending crises.

But what of the application of computers to tasks in biological research that have hitherto been beyond the scope of conventional techniques?

Many of the innovations in the past few years are comparable with those in other fields. It is unthinkable that X-ray diffraction data should, these days, be analysed by the traditional methods, and computer techniques are used as a matter of routine in construction of the models of most molecules, biological or otherwise. Quite apart from the way in which computing machinery has given people the courage to tackle problems that would otherwise have been neglected, the more economical use of data has made it possible to work with lower X-ray intensities.

Another development of this kind is in the construction of molecular models. Modelling biological molecules of any complexity is a formidable task, and this is the principal incentive for the development in the past decade or so of computer programs which can handle such tasks quickly but, more important, can in principle explore all possible configurations of a complicated molecule.

These are essentially data-handling tasks. The most recent development of this kind has been prompted by the sheer size of the nucleotide sequences now being accumulated. It is natural that these should be stored in computer form, and plans for the development of such a computer bank have been discussed between the National Institutes of Health in the United States and the European Molecular Biology Organization. One obvious elaboration of such a system is the use of computer programs for searching nucleotide sequences for particular configurations of nucleotides, for example for configurations that define the points of action of particular restriction enzymes. But the construction of a complete nucleotide sequence is not always straightforward, given that it may have to be inferred from the nucleotide sequences of overlapping fragments of a complete DNA molecule, which is why there are now ambitions to solve such essentially combinatorial problems by using computing machinery. □

Computer model of the protein crambin

Computers cheaper

One of the most surprising additions to the language brought about by the use of computers in high-energy physics is the verb "to Monte Carlo". (It is not clear whether the root of the verb should be hyphenated.) The verb is a reference to the now standard procedure by which somebody planning a high-energy physics experiment must recognize that he will not get the grant he needs unless he has first simulated the efficiency of his detector set-up by means of a computer calculation. The principle is that the path of any particle through the sequence of detectors and other recording devices that may be involved in an experiment will not only depend on the origin and momentum of the particle within a beam (whose dimensions are never negligible) but also on the strictly statistical chance that it will interact or decay at some stage. Analytical calculations are rarely possible; instead physicists use Monte Carlo calculations, in which the hypothetical paths of individual particles with parameters chosen by means of random number generators, and chances of interaction similarly determined, are followed through the equipment in the computer simulation. Successful applicants for grants and successful experimenters know that much depends on the skill with which their experiments have been "Monte Carloed" in advance.

This, however, is a relatively indirect use of computers in the high-energy physics laboratories. A much more direct use of computing machinery is in the control and management of experiments, and here perhaps the most striking application of computer techniques is in the control of the beam of 400 GeV protons in the SPS proton synchrotron at CERN.

The CERN system

The problem is easily stated. The machine consists of a vacuum chamber arranged roughly as a spherical ring 2,000 metres in diameter. The circulating beam of protons is intended to have a fixed orbit within the vacuum chamber while, to prevent collisions with the walls of the vacuum chamber and thus the loss of protons, the diameter of the beam itself should be of the order of 1 centimetre. But the beam circulates in the form of a pulse or package of protons, thereby increasing the electrostatic repulsion between them and adding to the inevitable space charge whose consequence is further to spread out the proton beam.

To avoid this difficulty, the proton synchrotron has been provided with a control system consisting of magnets for correcting the position of the beam within the vacuum chamber based on signals picked up by detectors elsewhere in the ring. It is tempting to describe this as a way in which the position of the beam is

adjusted in the light of information about its characteristics a few microseconds earlier, at the other end of the 2,000-metre diameter ring. In practice, of course, that description is an over-dramatization. It is entirely possible to accommodate departures of the proton beam from its intended position, or its spread beyond the intended width, for several orbits around the ring.

Computer control

Inevitably the beam adjustment has to be controlled by a computer. While in principle the system is not markedly different from those which make decisions on the ways in which detection equipment should operate based on observations of the properties of a particular particle entering the equipment, there is a sense in which the development of these systems has helped to make very high-energy accelerators feasible — or at least to reduce their cost or to improve their efficiency. The quality of a beam, after all, depends on its intensity (the number of particles in a single pulse) and on its small dimension. Too many particles lost in collision with the walls means too much beam intensity sacrificed. But the obvious solution to this problem, to use a larger vacuum chamber or stronger focusing magnets, adds

enormously to the cost of what is, after all, the most expensive part of such a machine, the magnet system in the poles of which the vacuum chamber sits.

Inevitably, such sophisticated control systems, already in use at CERN and at the Fermilab in the United States, will be incorporated in all large machines built in the years ahead. When funds are hard to come by, and when high-energy physicists must necessarily be seen by their sponsors to be making all possible economies in their proposals, it is clearly advisable to spend a little money on the computer control of the particle accelerator so as to save what may be a substantial percentage of the total cost of electromechanical construction.

Bubble chambers

These uses of computing machinery in high-energy physics are inconspicuous although now familiar. During the past 20 years, however, one of the most eagerly sought developments has been that of the computerized handling of the photographs of the tracks left by charged particles in bubble chambers — the modern versions of the Wilson cloud chamber. Tracks in bubble chambers consist literally of strings of bubbles forming in, say, liquid hydrogen at points where electrical ionization has been created. Especially with the improvement of accelerating machines and the inexorable trend towards higher energy, bubble chamber photographs (which come in stereoscopic pairs or

A sixteen-bit microprocessor — many thousands of transistors on a ¼ square inch of silicon

Texas Instruments Ltd

...multiples) consist mostly of uninteresting tracks left by particles which have passed through the chamber unaffected (although perhaps deflected in one direction or the other, according to their charge, by the external magnetic field of a magnet). Traditionally, the analysis of such photographs, like the analysis of tracks in photographic emulsions, has been carried out in high-energy physics laboratories by small armies of part-time workers, usually women. Pressure to computerize the task of analysis has arisen not merely for economic but also for managerial reasons. A complete analysis of all the interactions recorded on a single bubble chamber image is too great to be attempted except in exceptional circumstances. The first attempts at simplifying the task required that the human operator should follow only tracks judged to be interesting with some device whose position in two directions could be recorded automatically, by pressing a button perhaps, stored in digital form and analysed to give a 3-dimensional reconstruction of the track.

In the past 15 years, however, the analysis of the complicated sets of images of which only some are interesting has been further simplified by the development of the so-called Hough-Powell device, essentially a means of scanning a plate or of scanning an image photometrically with a flying laser spot constrained on a predetermined raster. A digital output is thus provided in a simple form — each spot on the image is either black or white.

Limitations

In principle, appropriate analysis of two stereoscopic photographs of this kind can reconstruct the tracks of all charged particles passing through a bubble chamber. In practice, even with the use of computer hardware, the task is too slow and too demanding of storage space. Accordingly, it is still standard procedure for somebody, by means of visual inspection, to select those particular tracks in an image which are interesting enough to justify detailed analysis. One by-product of these computer systems is that they yield not merely a detailed geometrical reconstruction of a track but also a kinematical analysis of those particles involved. Whether they will ever be capable of operating entirely automatically, ignoring uninteresting tracks and singling out those which, by predefined criteria, are especially interesting or significant is another matter — and a problem in pattern recognition.

The development of these systems has been to an encouraging extent a collaborative business, in which the large high-energy accelerator laboratories have played a central part. In Europe, for example, one direct result of this collaboration has been the development of a set of standards (called CAMAC) intended to ensure compatibility of information processing equipment. □

Logic circuits before computers

When nobody was especially well supplied with equipment, but when nuclear physicists were better supplied than anybody — in the late 1940s and early 1950s — it was relatively easy to predict who the first users of computers would be. It is tempting to think, at least where the nuclear physicists are concerned, that they learned their habits during the Manhattan Project. In truth, the search for ways of applying computational techniques to the task of observing what you want to observe and not some tedious background signal came two decades earlier, in 1931.

Then, for practical purposes, there were merely a handful of techniques for observing the effects of energetic charged particles, one of which consisted simply of measuring the rate at which a charged electroscope would lose its charge. The most interesting technique was C.T.R. Wilson's cloud chamber, which had for the first time made it possible to visualize the tracks of charged particles travelling through its confined volume, but which to begin with could take snapshots of the flux of charged particles through it only at randomly chosen intervals. The chance of finding something interesting cannot have been much greater than that of finding a needle in a haystack.

Geiger counters, also widely used in the 1920s, were more discriminating than cloud chambers in that they would produce an electrical discharge only if the energy of the charged particle traversing them was greater than a certain amount determined by the quantity of precise composition of the gas with which the vacuum was filled — so much argon, so much nitrogen and so on. The snag with a Geiger counter (1930s vintage) is that it was simply a device for answering "yes" or "no" to the question "Where (and when) did a charged particle with more than the threshold energy pass by?"

But what more natural than to couple a layer of Geiger counters connected in parallel to the expansion mechanism of a cloud chamber so as to ensure that the cloud chamber photographs would include the track of at least one charged particle whose energy was greater than the threshold energy? This, in 1930, is what P.M.S. Blackett and G. Occhialini (then at the Cavendish Laboratory) set out to do. Blackett used ruefully to complain that if Occhialini had not taken a long holiday, they would have found the positron before P.W. Anderson.

From that point on, the use of elementary logic circuits, answering "yes" or "no" to questions such as "Has such and such a kind of charged particle passed through?", was inevitable. Arrays of Geiger counters working in coincidence ("A charged particle went in and another came out the other side") or

in anti-coincidence ("It went in, but nothing came out") were all the fashion. Chadwick proved the existence of the neutron by such a technique.

By the outbreak of the Second World War, people's ambitions had grown, while detection techniques had become more complicated — sophisticated is hardly the word. By encasing cloud chambers in magnetic fields, and arranging that the chamber would not be triggered into action unless a charged particle "went in" and emerged virtually unchanged in direction (indicating that its energy was very large), it was possible to ensure that all cloud chamber photographs included at least one track of an energetic particle (which is how the "strange" particles of matter were eventually discovered, in 1948).

Long before then, however, logic circuits and the development of detecting devices had made it possible not merely to

P.M.S. Blackett

record the arrival of a charged particle but to assign it to some range of energy. The outputs from the devices used for such purposes were essentially digital, so why should they not be accumulated in digital form? This is how it came about that nuclear physics laboratories in the 1950s, but especially those connected with semi-secret enterprises, were the first to be blessed not merely with huge racks of electronics fitted out with tube-driven logic circuits but with slave electric typewriters as well, recording the data the detectors generated. (Most secretaries in those same laboratories still used manual machines.)

Frivolity apart, the outcome has been important. The high-energy physicists have been among the leaders in the use of computers for the control of experimental equipment. Most of the detection equipment now run in connection with high-energy particle accelerators consists of an elaboration of the counter-controlled cloud chamber now exactly half a century old. The difference is that the primitive logic circuits of the old devices have been replaced by computing machinery. □

Astronomy by numbers

Computers have taken astronomy by storm in the past decade or so, and for obvious reasons. Need has been matched by opportunity, but astronomers have also been temperamentally attuned to computerization by the space programmes of recent years. Once it became necessary to work with data transmitted in digital form by telemetry from rockets and satellites, it was certain sooner or later to become habitual to use the same techniques for dealing with other sources of data.

Astronomy has traditionally been profligate in its regard for data. A single plate from a large Schmidt camera, covering a patch of sky just six degrees in each dimension, may include up to 10^6 images of different kinds. Merely recording the positions of these images would occupy a skilled technician for the best part of a lifetime. The libraries of the world's observatories most probably contain enough information to keep the world's astronomers usefully employed for the rest of their lives — perhaps on problems of no particular interest.

The simple solution to the problem of counting stars and measuring plates is similar to that to which high-energy physicists were forced in the 1960s, when it became impracticable to measure the tracks of fast particles in bubble chambers

by hand and eye. The first need is a device for converting star images into numerical records of the density of exposure at different points on a plate. Plate reading systems have been developed at several observatories. As always, the tricks lie not in the hardware but the software — in this case the rudimentary programs for telling which image is what. Is it a star? Or a galaxy (and if so which kind)? Or something else?

One neat way of describing the benefits of these systems is that it has taken some fifty man-years of programming time to develop the software used with the COSMOS plate measuring system at the Royal Observatory, Edinburgh and that the result is to make possible the measurement of the images on a single Schmidt plate in one day, not one lifetime (also fifty man-years). This figure of merit is also an index of the true cost of these devices — £500,000 is probably an underestimate of the true cost of developing COSMOS.

The other component in the recent computerization of astronomy is the digitization of the data base. The most striking illustration so far of the benefits of this technique is the Einstein X-ray satellite (now, happily and surprisingly, restored to working order). The essence of the X-ray telescope is a system of conically shaped

glass surfaces from which X-ray photons are deflected at more or less grazing incidence. The detectors are inherently electronic, borrowed from nuclear physics. So the data are inherently digital in form, literally consisting of the spatial coordinates in the image plane of individual X-ray photons. So why not record not merely the angle from which these photons have arrived but the time of their arrival and even information about the energy of the incident photons?

In practice, the Einstein satellite is equipped with a variety of X-ray detectors which separately provide different kinds of data. The detector with the highest resolution, called the High Resolution Imager, is designed to record the arrival of X-ray photons on the MgF_2 plates from which cascades of electrons are generated to within 1 second of arc and within 8 milliseconds. The working spatial resolution of the instrument is less than this (some tens of seconds of arc) because of the properties of the mirror system, but this high resolution instrument provides no spectral information worth speaking of, with the result that the computer systems store merely spatial and temporal information.

Other instruments in the Einstein Observatory, which can generate spectral information (but whose spatial resolution is not as high), yield data streams from which spatial, temporal and spectral information can be regenerated. The

Some things old, some new

Electronic computers are merely the latest stage in the computerization of the laboratory. The earliest aids to laboratory computation were probably the astrolabes and armillary circles going back to the antiquity of astronomy. The first explicit

aids to laboratory computation were probably Napier's logarithmic systems of coloured rods (called "bones") introduced early in the seventeenth century, and quickly followed by Pascal's logarithmic scale, much used (with the help of a pair of dividers) by navigators in the eighteenth century.

The needs of astronomers stimulated interest in what may have been the first computerized aid to laboratory observation — sky-following telescopes. Robert Hooke appears to have been the first to have conceived of this innovation, but his proposal for a clockwork-driven telescope was built for G.D. Cassini at the Paris Observatory and commissioned in 1682. This was a huge device, with the objective mounted at the centre of a clockwork-driven structure and with the

eyepiece mounted separately at a distance of more than 100 feet. Cassini's telescope was known as his *machine parallatique*.

Attempts at the further development of clockwork-driven telescopes appear to have been few and far between in the eighteenth century. Such instruments seem to have come into their own only in the early decades of the nineteenth century.

Dr John Darius (Science Museum, London) writes:

Driving telescopes around their polar axis to follow the diurnal apparent motion of the stars is useful for visual observations but absolutely vital for astronomical photography. The earliest drives, dating from the beginning of the nineteenth century, were purely mechanical, depending on a clockwork mechanism driven by weights to rotate the telescope in the equatorial plane at the rate of 15 degrees of arc every hour. By around 1870, telescope drives regulated by an electric pendulum clock had been invented, but by 1910 electric motors were coming into regular use. Nowadays digitally controlled synchronous motors as uniform as the frequency of the mains supply have almost wholly replaced their historic forebears. The most modern systems now use servomechanisms which are controlled by computer. □

W.H. Smyth's clockwork-driven telescope, 1829

An image of comet Bradfield taken by the Fine Image Sensor of the IUE satellite observatory

practical value of this complication is that some X-ray sources are especially interesting because of their rapid fluctuation with time. Thus some X-ray sources that consist of binary star systems in which material is being transferred from one star to the other intermittently fluctuate in X-ray intensity on time-scales of a few minutes. Others, for example quasars, also fluctuate in time. Some of the earliest observations with the Einstein Observatory (see, for example, Tananbaum, H. *et al.*, *Astrophys. J. Lett.* **234**, L9; 1979) were used to demonstrate variability of X-ray intensity from distant quasars over a period of a few hours on the basis of a mere 50 or so X-ray photons.

It goes without saying that the planning of a series of observations with such a satellite requires that the on-board computers should be explicitly instructed on what information to store, and in which form, while the planning of the way in which a high-resolution instrument scans a small patch of sky requires some forethought about the way in which the data will be analysed. Programs by which the field of view moves in overlapping steps across the sky are often advantageous. It is commonplace that observations of particular objects are pre-programmed not for arbitrary periods of time but in such a way as to yield statistically significant results (which entails concurrent measurement of the background radiation).

Astronomy as a whole now seems destined to move in these directions, helped by the development of a variety of detection devices whose chief purpose has been to improve the sensitivity of telescopes (optical, radio, infrared, what-have-you) but which as a by-product yield a stream of numbers as the crude data. Quite what balance will in the end be struck between positional, spectral and temporal information is, however, still very much a matter for astronomers to decide. For the plain truth is that while it may in principle

be possible to record every detail of every quantum event occurring at the light-sensitive surfaces of the image intensifiers, there is no hope of being able to store such a wealth of data.

Accordingly, there is no sense in which the computerization of astronomy can be said to have robbed the craft of the need for discrimination and judgement. Although the coming of more efficient light detectors has often made possible dramatic reductions in the length of time needed to gather significant information about some distant object, observing time is still at a premium. The need for deciding clearly in advance what questions it is hoped to answer, and for collecting the smallest amount of data required, has therefore not diminished. Indeed, it has been intensified by the ease of discrimination in the collection of data.

The bugbear that remains is that the craft has become almost inextricably bound up with computer programming. Research students have repeatedly found themselves caught up in projects for writing programs to recognize, say, elliptical galaxies, or to measure the ellipticity of globular clusters. Educative though these exploits may be, there is obviously a danger that too much creativity may be lavished on what is essentially repetitive work.

This is part of the incentive for the development in the United Kingdom of a linked network of six astronomy centres in a project funded by the Science Research Council under the trekky name of STARLINK. The plan is that five British centres (the Royal Greenwich Observatory, the Royal Observatory Edinburgh, University College London and the Universities of Manchester and Cambridge) should be provided with identical computer systems and linked by low-capacity data links to a coordinating centre at the council's Rutherford-Appleton Laboratory.

The objective is to make possible the more economical use of people's pro-

gramming energies. Schemes for the development of novel programs will be worked out on an *ad hoc* basis by the collaborating laboratories. Programs but also images (containing 500×500 picture elements or pixels to begin with, perhaps 16 times as many later on) can be transmitted from one centre to another. There are some ambitions that the system may be extended internationally, to Europe, possibly the United States and, with luck, to Australia.

The STARLINK system is interactive in that the DEC VAX computer system provides astronomers with a graphic display of an image which can be manipulated this way or that, to yield profiles across an object for example. Much of the work so far, however, has been the development of programs for the analysis of spectra. How does one extract from a record of intensity as a function of wavelength numerical data for line frequencies and line depths? Superficially, the problem resembles that which crops up in quite different fields. In medical physics, people are forever trying to decide how best to characterize heartbeats.

The system is not yet fully a going concern, although it is hoped that a full package of software will be available "in months rather than years". For some purposes, however, the response of the system is plainly not fast enough — people who want to follow the motion of features in the atmosphere of Jupiter, for example, need more sophisticated image processing, with a much faster response. This is why, for instance, some of those concerned with the processing of data from the recent series of planetary probes have independently developed more sophisticated image processing systems. One such is the IPSIS system at University College London, which gives scientists access to a large number of satellite images stored in digital form. The interactive nature of the system permits a detailed examination of all aspects of the data. □

Algebra made mechanical

The notion that computers are mere number crunchers is fast being exorcised by one small group of people — the computer algebraists. In the past twenty years, several classes of problems which require analytical and not numerical solutions have been tackled successfully. Now, for example, there are computer programs that can yield analytic expressions for indefinite integrals a good deal more reliably than the "random undergraduate", as one practitioner puts it.

Neither the need nor the feasibility of these tasks is self-evident. And, as things are, the community of computer algebraists is small and scattered. Yet, in some fields, it is now commonplace for people with time-consuming algebraic calculations on their hands to use a computer program for the purpose. And

the fields in which these techniques are being used are so diverse that there seems every prospect that computer algebra will spread.

The feasibility of computer algebra is demonstrated easily enough — perhaps most easily by the manipulation of polynomial expressions such as $a + bx + cx^2$. Adding second-degree polynomials together requires an algorithm for adding together the coefficients. Multiplication and subtraction are similarly straightforward. Division is (as always) more difficult, but there is no reason why the rules of school algebra should not again be applicable.

Producing analytical forms of indefinite integrals, or analytic solutions to differential equations, is necessarily more difficult, not merely because the computer

programs used for these purposes must in some sense "know" the essential mathematical properties of functions such as $\sin x$ or e^x , but also because the analogy with the way in which students are taught to solve such problems (by classification around solvable standard forms) is not sufficiently general.

Yet programs for these purposes have been developed at several centres. Put to work on sets of problems taken from standard textbooks, they typically yield success rates of 97 or 98 per cent — they have more than the competence expected of undergraduates but are not yet good enough to satisfy the purists. But these, of course, are not the fields in which computer algebra is likely to make its mark.

There are many more telling applications of the technique, in fields where in the past heroic individuals have battled with forbidding mountains of algebra or have, as likely as not, decided that discretion is the better part of valour.

The successes

One of the first and most striking successes in this field was in celestial mechanics — the theory of the Moon. The problem is straightforward but daunting. Since Newton's time, a knowledge of the geocentric longitude of the Moon as a function of time has been an essential ingredient of the craft of navigation. To state the problem is simple enough — it is a classical problem in Newtonian mechanics. It is, however, a three-body problem even without the gravitational effects of Jupiter and the other planets and is thus incapable of yielding an exact solution.

In the circumstances, only perturbation methods of solution will suffice. Numerical solutions, widely used, have one serious and for some purposes insuperable drawback — errors accumulate horrendously as the span of the time variable increases, so that it is not, for example, possible to be sure of where and when some past eclipse should have occurred. Accordingly, there has always been great interest in analytical solutions of the problem of the Moon — essentially approximations in the form of convergent series whose terms are individually analytical.

The only successful attack on the problem "by hand", so to speak, was that of Delaunay, whose two huge volumes on the subject were published by the French Academy in 1860 and 1867. The first hundred pages of the first volume are entirely given over to a representation of Delaunay's analytical expression of his "disturbing function" (essentially the departure of the gravitational potential of the Moon from simple Newtonian calculations of the potential due to the Earth). This seems to have represented literally a lifetime's algebra — Delaunay carried through his calculations to the seventh order in small quantities. Now, the same

calculation can be run on a computer in a few tens of seconds, and to a higher order of approximation. Delaunay's descendants need not be ashamed that the first computer programs showed that his algebra had not been immaculate.

Similar analytical solutions of more intricate (and previously intractable) problems in celestial mechanics are now matters of routine — for example, the movement of putative Earth satellites about the Lagrangian points at which the gravitational forces of the Earth, Sun and Moon cancel out. The practical importance of these developments is considerable, if only because the error of an analytical approximation is more easily assessed than that of a numerical approximation.

General relativity

Curiously, as it may seem, one of the other well tried (and much used) applications of computer algebra is in general relativity the problem is this. Einstein's general theory of relativity is general in the sense that it is possible to derive the gravitational field equations, typified, for example, by the gravitational forces on a test particle itself of negligible mass from an analytical expression for the metric of space-time. The simplest possible form of the metric is

$$ds^2 = dx^2 + dy^2 + dz^2 - c^2 t^2$$

where c is the velocity of light, x , y and z are cartesian coordinates and t is time. Substituting this metric into Einstein's general theory merely recaptures the kinematic aspects of special relativity, as of course it should.

More generally, the metric of space-time is written

$$ds^2 = G_{\mu\nu} dx^\mu dx^\nu$$

where the indices μ and ν run from 1 to 4, x^μ is one of the four coordinates of space-time and the quantities $G_{\mu\nu}$ are, in general, functions of these coordinates. The underlying convention adopted by the relativists is that indices which occur twice represent summations — in other words, the general metric consists of 16 terms of which the first is

$$G_{11} dx^1 dx^1 = G_{11} (dx^1)^2$$

Regarded as a general theory, the General Theory is intractable. The field equations, the differential equations which predict how particles should behave, are nonlinear and therefore soluble only with special assumptions. So the standard way of tackling problems in general relativity consists either of guessing that a metric might illustrate some particular property of a gravitating universe, and to calculate from that the field equations, or alternatively to look for approximate solutions of the field equations, valid in some narrow regions of space and time. In either case, the hapless relativist finds it necessary to calculate what are called the Christoffel symbols of which in general there are 64, each of them a combination of three first partial derivatives of the functions which define the metric. That, however, is only a

beginning. The next step is to calculate the Riemann-Christoffel tensor, which is in general a tensor with 256 distinct components, each of which is a linear combination of partial differential coefficients of the Christoffel symbols.

The sheer algebraic complexity (and tedium) of these calculations explains why only a few relatively simple metrics have been used in general relativity. Even the simplest of the more general metrics, the general case of an orthogonal metric

$$ds^2 = D(dx^4)^2 - A(dx^1)^2 - B(dx^2)^2 - C(dx^3)^2$$

in which the symbols D , A , B and C stand for functions of the four coordinates x^i etc. presents formidable problems of computation. Herbert Dingle in 1933 published a list of the Christoffel symbols (*Proc. natn. Acad. Sci. U.S.A.* **19**, 559; 1933) which represented the fruit of several years work and which remains a standard reference list. The likelihood that such calculations would now be attempted with more general metrics is exceedingly small, which is why computer programs for making these calculations are widely used.

Probably the most widely used set of computer programs with applications in theoretical physics is, however, that called SCHOONSCHIP, developed in the late 1960s at CERN in Geneva as a means of calculating physical quantities in quantum electrodynamics. Briefly, such problems invariably create the need to calculate the trace (the sum of the diagonal elements) of a four-dimensional matrix which is itself the sum of what may be a large number of four-dimensional matrices obtained by multiplying together the so-called Dirac matrices. Although the elements of the Dirac matrices are simple (either 0 or 1), the algebraic task of computing by hand the product of say eight of them is enormous, and the chance of making a mistake is very great. (In practice, the multiplication of Dirac matrices goes hand in hand with the evaluation of four-dimensional integrals, now also computerized.) In some applications, as for example in the application of similar techniques to unified field theories or quantum gravity, many vital calculations have not been carried out simply because of the complexity of the task. Inevitably, with the passage of time, programs such as SCHOONSCHIP have therefore become widely used.

Versatility

These three applications in theoretical physics of computer programs are tangible and valuable. But if the object of computerizing algebra is to provide theoretical physicists with what Professor Joel Moses has called an algebraic assistant, surely computer systems should be more versatile. This consideration underlies the attempts which have been made since the late 1960s to develop general-purpose algebraic computer programs, the best known of which is called MACSYMA

and lives in a PDP-10 computer at the Massachusetts Institute of Technology (MIT). A similar computer system called REDUCE was developed during the same period at the University of Utah.

In principle, these programs are designed to deal with whatever algebraic problems may be thrown at them. In their development, handling polynomial algebra and matrix multiplication was relatively straightforward. The problem of integration, requiring that the program should make decisions about the most appropriate way of solving a problem, was necessarily more difficult. Even differentiation creates problems when irrational functions are involved. Now, however, MACSYMA has more than a thousand users, many of whom make use of it by means of international communications systems such as the ARPA network. Versions of the program are soon to be made available in a dialect of the computer language LISP, when MACSYMA is likely to be as easily available as its competitor, REDUCE.

Data stores

Inevitably, with such ambitious programs, the storage capacity required is very large. For practical purposes, the program has to be provided with a comprehensive knowledge of mathematics. Professor Moses estimates that MACSYMA at present uses a million 32-bit words of storage capacity but users may be able to get by with less if they make do without some of the more general functions.

Storage capacity appears to be a recurring problem in computer algebra, not merely for comprehensive systems such as MACSYMA and REDUCE, but also for more straightforward algebraic programs. The reason is easily understood. If the objective, for example, is to compute the polynomial expression $(a + bx)^n$, it is clear that the result must be a polynomial of degree n with $n + 1$ distinct coefficients. But the number of terms that arise by multiplying together one of the two elements in each of the n factors is 2^n . If n were anything like as large as, say, 100, it would be physically impossible to store the terms separately in the computer. In practice, of course, this particular computation is straightforward. But the problem of storage does compel the designers of algebraic programs constantly to be on the lookout for algorithms that make economies. For the simple binomial expansion above, for example, it plainly makes sense that the factors should be multiplied together consecutively. Nevertheless, program designers have found it necessary to provide overspill storage in case a problem should have need of it, often by means of buffer storage on magnetic tape which has then to be searched regularly and reincorporated in the accessible memory of the computer if the program so decides.

Users of both comprehensive programs such as MACSYMA and more specialized

Plenty of programs

Altogether there are probably more than 50 computer algebra systems now available. The following are the best known or most widely used.

- **MACSYMA.** Developed since 1968 at the Mathlab at the Massachusetts Institute of Technology by Professor Joel Moses and his colleagues. The objective has been a comprehensive system, capable of solving all algebraic problems. Development continues. Hitherto the system has been accessible only at MIT but the program is soon to be made available to outside purchasers. It is slower in specialized applications than purpose-designed computer programs.

- **REDUCE.** Largely developed by Professor A.C. Hearn, originally at Stanford University and then at the University of Utah. (Hearn is now at the Rand Corporation, Santa Monica.) The objective is a comprehensive system. Development has been dependent on collaboration and, collaborators say, has profited therefrom. The program is usable on a variety of machines (although some would-be users have found that adaptation is difficult). The system is still being defined and made more comprehensive. Users say that newly available programs are much more sophisticated than earlier versions.

- **SCHOONSCHIP.** Developed by Veltman at CERN in 1972 with the objective of solving problems in quantum

electrodynamics. Within its range of applications the system is fast and its demands on computer storage modest. The program is easily usable on large CDC computers but less easily on machines of smaller word length.

- **CAMAL.** The system developed at the University of Cambridge in the 1960s for solving problems in celestial mechanics. Fast for what it does and modest in demands on storage. Still widely used but now losing ground to more sophisticated systems, for example that developed by the Boeing Space Sciences Division.

- **MUMATH.** Developed by Stoutemyer at the University of Hawaii and intended for use with microprocessors. Suggested uses include teaching but also an application to small research problems, and in particular for system design.

Most computer manufacturers have algebraic programs as do the Bell Telephone Laboratories.

Such coordination as there is of academic interest in algebraic computing is undertaken in the United States by SIGSAM, a special interest group of the Association for Computing Machinery, which organizes meetings (the next at Snowbird, Utah in August this year) and which also publishes a quarterly bulletin. In Europe, coordination is through the Symbolic Mathematics Committee, organized by J.A. van Hulzen (T. Hogeschool Twente, Enschede, The Netherlands). □

systems such as SCHOONSCHIP testify to the complementarity of the two kinds of systems. The comprehensive systems are inevitably slower than the specialized systems and also less convenient to use in practice. On the other hand, access to the comprehensive systems can be of great value in the amendment of an existing program. Users also say that there are pitfalls to be avoided when programs such as REDUCE are purchased on magnetic tape and used with computing machinery different from that on which they were originally developed, which is part of MIT's justification for not hitherto making MACSYMA widely available.

Curiously enough, although the algebraic computer programs are in general demanding of computer storage, they are relatively undemanding of programming time. MACSYMA, largely the product of people working at MIT since 1968, is estimated to have taken between 50 and 100 man-years of programming effort. Other systems designed for specialized purposes can be relatively simple to design and write. One practitioner, for example, says that the time required to write a program for simple polynomial algebra is not much more than a quarter of an hour. No doubt the relatively undemanding nature of some of the programming required reflects the character of the problems to which

computer algebra has so far been applied — their intrinsic tedium. And, of course, nobody pretends that writing programs to carry out integration, to solve differential equations or to tackle problems in mathematics such as the enumeration of finite groups can be solved in a straightforward way.

What the future holds for the applications of computer algebra remains to be seen. Already, however, some of the practitioners hold that the availability of these techniques provides a means by which shortages of mathematics teachers, even at the school level, might be remedied. Indeed, the University of Hawaii has developed a computer algebra program (commercially available) that can be run on home computers, while there are ambitions to use MACSYMA in the education of undergraduates.

What educationists will have to say about this prospect is unclear. The hand calculator, once considered a threat by elementary school teachers, seems now to have been recognized as a stimulator of interest. It is harder to see how more formal computer programs will be used in teaching algebra, and it is widely thought that too indiscriminate use of computers for algebraic computations in research may blind users to the physical significance of what they are doing. □

REVIEW ARTICLE

Can dietary beta-carotene materially reduce human cancer rates?

R. Peto*, R. Doll†, J. D. Buckley‡ & M. B. Sporn§

Human cancer risks are inversely correlated with (a) blood retinol and (b) dietary β -carotene. Although retinol in the blood might well be truly protective, this would be of little immediate value without discovery of the important external determinants of blood retinol which (in developed countries) do not include dietary retinol or β -carotene. If dietary β -carotene is truly protective—which could be tested by controlled trials—there are a number of theoretical mechanisms whereby it might act, some of which do not directly involve its 'provitamin A' activity.

THE possibility of discovering anticancer substances that can be prescribed rather than carcinogens that must be proscribed is attractive, for people may be more willing to accept prescription than proscription. If inhibitors of the late 'stages' of neoplastic transformation could be found, they would have the added advantage of conferring their benefits without an impracticably long latent period. Since there is growing evidence that retinoids and perhaps also carotenoids can be anti-carcinogenic, we review the intake and metabolism of 'preformed vitamin A' (retinal and retinol and its esters) and of the carotenoids (some of which exhibit 'provitamin A' activity), and we review the epidemiological evidence correlating blood levels or dietary intake of one or other of these with low cancer risks. Two independent questions will be considered.

First, within the range of variation of total blood retinol levels consistent with the avoidance of hyper- and hypo-vitaminosis A, is there any material variation in human cancer risks attributable to a protective effect either of unbound retinol or of carrier-bound retinol in the blood, and, if so, what are the important extrinsic determinants of the concentration of carrier-bound retinol in human blood? (Paradoxically, within the wide range of dietary intake rates consistent with avoidance of both hyper- and hypo-vitaminosis A, the amount of retinol derived directly or indirectly from the diet makes no material difference to the blood levels of carrier-bound retinol.)

Second, within the range of blood levels of β -carotene (or some other carotenoids) which are insufficient to cause cosmetically unacceptable skin yellowing, is there any material variation in human cancer risks attributable to a protective effect of circulating carotenoids, and, if so, what are the important extrinsic determinants of the concentration of β -carotene and other carotenoids in human blood? (In contrast with blood retinol, blood carotenoid levels are directly determined by dietary carotenoid levels, although they may also be affected by certain chronic disease states.)

The evidence relating to the above two questions will be reviewed under three headings:

(1) The qualitative difference between the pharmacodynamics of β -carotene and of retinol¹⁻³ in the human body: which

suggests that the possible relevance of these two components of 'dietary vitamin A' to cancer prevention should be assessed separately.

(2) The inhibition by retinol and various synthetic retinoids of the later, rather than the earlier, processes of carcinogenesis in experimental studies with animals and cultured cells: which suggests that if such agents have any substantial anticancer effects on humans, a reduction in risk should be measurable within about 5 years, instead of after a latent period of some decades, as might be expected for inhibitors of the 'early' processes of carcinogenesis.

(3) The tendency, observed in many epidemiological studies, for some human cancer risks to be inversely associated with blood retinol, and with blood or dietary β -carotene.

Pharmacodynamics

'Vitamin A' is a nonspecific term embracing two different families of dietary factors, one family comprising the various types of 'preformed vitamin A' (chiefly retinyl esters, but also retinol and retinal), and the other family comprising the various types of 'provitamin A' (chiefly β -carotene, but also those other carotenoids that can be metabolic precursors of retinol). If retinal (the aldehyde $C_{20}H_{28}O$) is written $X=O$, then retinol, the corresponding alcohol, is $H-X-OH$, and β -carotene is the polyunsaturated hydrocarbon $X=X$, which may be oxidized by the enzyme dioxygenase to two molecules of retinal, chiefly in the intestine but perhaps also in the liver⁴.

The various types of preformed vitamin A are converted efficiently by the human body into retinol, and a variable fraction of dietary β -carotene is converted in the human intestine into retinal. Nutritionists estimate² that even among poorly nourished people β -carotene usually yields only about one-sixth of its weight of retinol; furthermore, the fraction converted decreases as the amount of β -carotene in the diet increases so that even massive doses of β -carotene will not yield enough intestine-derived retinol to cause systemic toxicity ('hypervitaminosis A'), unless massive amounts of preformed vitamin A are also taken. Despite this inefficient intestinal conversion of β -carotene, and the even less efficient intestinal

Caution

Unwary readers (if such there are) should not take the accompanying article as a sign that the consumption of large quantities of carrots (or other major dietary sources of β -carotene) is necessarily protective against cancer, and the correlation between blood retinol and cancer avoidance is, for the time being, *sub judice*.—Editor, *Nature*.

Table 1 Prospective studies of cancer in relation to total blood retinol in stored blood samples taken from apparently healthy people

Country	Relative risks (in sequence from low to high blood retinol quintile)					No. of cancers (all sites)
	5.3:	2.9:	3.8:	3.0:	1*	
Georgia, USA ³¹	5.3:	2.9:	3.8:	3.0:	1*	85
United Kingdom ³²	2.2:	1.7:	1.6:	1.1:	1	86

* Top quintile based on only seven cancers, and so unreliable.

conversion of most other carotenoids, many people in rich countries and most people in poor countries derive the majority of their retinol from the provitamin A carotenoids in plants. However, some of the dietary β -carotene and other carotenoids is absorbed unchanged from the intestine, circulates around the body, and, being fat-soluble, is stored in adipose tissue. Various factors then affect its metabolism and excretion (for example, diabetes⁵, thyroid disease⁵ and, paradoxically, anorexia nervosa^{6,7} will elevate blood β -carotene levels), but other things being equal blood and adipose tissue levels of β -carotene and other carotenoids are directly related to the amounts ingested over the preceding few weeks⁸. Normally, a daily average of only a few milligrammes of β -carotene is consumed. This makes human fat appear yellow but is not sufficient to cause noticeable yellowing of the skin. However, if a few dozen milligrammes of β -carotene per day are consumed for several weeks by Caucasians, 'hypercarotenaemia' may develop, that is, skin yellowing may become cosmetically noticeable. No medically significant side effects of hypercarotenaemia are known⁹, and the condition disappears within a few weeks of reversion to a normal diet.

The mechanisms for storing, transporting and excreting retinol are more specific than those thus far discovered for β -carotene. Intestine-derived retinol enters the blood as 'unbound' retinol, esterified but not bound to the specific carrier protein for retinol (see below). Unbound retinol is rapidly absorbed from the blood by the liver, where it is stored. To transport controlled amounts of retinol from the liver to the peripheral tissues where it is needed, the liver synthesizes a carrier protein called retinol binding protein (RBP) at a rate which, unless the liver's stores of retinol are almost completely depleted, is not strongly dependent on the amount of retinol currently stored in the liver. (The total rate of loss of retinol from the liver is, however, directly dependent on the total amount stored in the liver^{10,11}, so other, presumably degradative, pathways must also exist, and will provide some homeostatic control against unlimited accumulation of retinol in the liver.)

RBP molecules can leave the liver as soon as they have picked up a retinol molecule from the liver stores; but if the liver stores are severely depleted RBP builds up in the liver, waiting for some unbound retinol to be derived from the intestine. This RBP build-up is characteristic of hypovitaminosis A, that is, vitamin A deficiency. At the opposite extreme, if due to regular heavy intake of preformed vitamin A the rate of derivation of unbound retinol from the intestine consistently exceeds the maximum possible rate at which the liver can get rid of retinol (both by steady carrier-bound release and by concentration-dependent degradation), the liver's retinol storage capacity will eventually be exceeded, damaging the liver and allowing significant amounts of unbound retinol (not bound to RBP) to circulate. This may lead to serious symptoms of hypervitaminosis A, since unbound retinol should never circulate in significant quantities except in brief transit from the intestine to the liver. However, most of the population of developed countries has a diet-derived intake of retinol within the wide range which avoids the well-defined physiological conditions of hypovitaminosis A (unbound RBP in the liver) and hypervitaminosis A (unbound retinol in the blood). Within this wide range, blood levels of carrier-bound retinol (retinol bound to RBP) are not materially dependent on the amount of free retinol derived from the intestine. For example, among Swedish acne patients an

increase of the normal dietary dose of retinol by a few thousand per cent for a few weeks increased carrier-bound retinol by only about 10% (ref. 12). Likewise, in New York, liver retinol levels, which are directly related to dietary intake rates, are uncorrelated with blood retinol levels¹³.

However, blood levels of carrier-bound retinol do have extrinsic determinants. For example, oral contraceptive users have substantially elevated blood retinol levels^{14,15}, and there are presumably also various other hormonal or non-hormonal determinants of the consistent differences between people in their long-term average carrier-bound retinol levels (including¹⁶ diseases of the liver, thyroid and kidney), although none seem to be well understood. The key finding for this whole review is that for most people in developed countries the amount of intestine-derived retinol is not one of the important determinants of the blood levels of carrier-bound retinol (or of total retinol, since free retinol is usually present in the blood only at much lower concentrations than carrier-bound retinol is).

Possible short latency of antitumour effects of retinoids and related compounds: The ICRDB¹⁷ have compiled summaries of some 324 cancer research papers concerned with retinol, other retinoids, β -carotene or other carotenoids, and the October 1979 issue of *Federation Proceedings* contains several further relevant papers. Together, these show that various retinoids can reversibly suppress the malignant behaviour of cultured cells that have been transformed by viruses, chemicals or ionizing radiation; they can delay or prevent the onset of cancer in experimental animals that have been treated previously with DNA-binding carcinogens; they can cause human skin keratoses or oral leukoplakias to regress; they can delay the appearance of transplanted tumours; they can prevent 'tumour promoters' from eliciting papillomas on mouse skin; and they can inhibit some of the very specific biochemical effects of tumour promoters on cells *in vivo* or in culture. Although inappropriate use of retinoids may do more harm than good¹⁸, it thus seems reasonable to hope that exposure of human tissues to retinoid-like activity can be manipulated to reduce cancer risks¹⁹.

Neoplastic transformation can often be subdivided into 'stages', the early stage(s) involving only partial alteration of a normal cell and the later stage(s) involving conversion of a partially altered cell into a fully neoplastic cell. Finally, to be effective the neoplastic cell must not be eliminated, and must proliferate into a pathological tumour. Early- and late-stage changes are both necessary (so halving either might be an equally effective way of halving cancer risks), but typically have different causes^{20,21}. The demonstrated protective effects of retinol (and, perhaps, β -carotene) are such as to suggest that it is the later stages of neoplastic progression which are chiefly affected, together perhaps with the final process of tumour growth. There might often be a latent period of a few decades before a doubling or halving of the early processes had any material effect on human cancer risks, but, to judge by the rapidity with which the effects of stopping smoking are evident, a doubling or halving of the late processes might have noticeable effects on human cancer risks within about 5 years, while effects on the final process (proliferation) might be even more rapidly evident. So, human cancer risks might be noticeably influenced by the average levels of blood retinol within a period of as little as 5 or 10 years. This conclusion greatly facilitates observational epidemiology and may even make practicable a randomized human evaluation of the anticancer effects of such agents (or of any other agents which inhibit either the late or the final processes).

By contrast with the retinoids, the question of whether dietary β -carotene or some other carotenoids can affect cancer risks has not received nearly as much experimental attention. Possible mechanisms to consider include (1) a direct retinoid-like effect of some carotenoid(s) on cellular differentiation in the target tissues, (2) conversion in the target tissue of some carotenoid(s) into molecules with some such retinoid-like effects, or (3) protection by carotenoids of the target tissues via mechanisms not

related to control of cellular differentiation (for example, by enhancing some immunological function^{22,23}, or by quenching singlet oxygen, a highly reactive excited molecular species which may be generated as a toxic by-product of many normal metabolic processes in both animals and plants: indeed, β -carotene is the most efficient quencher of singlet oxygen thus far discovered²⁴, and in plants the chief function of carotenoids may be to quench the singlet oxygen produced by photosynthesis²⁵). Before possible mechanisms are discussed, however, it must be asked whether any carotenoids have any general anticancer effects whatever.

We know of only nine experiments on the modifying effects of systemic β -carotene²⁶⁻²⁸ or of carrot extracts²⁹ on induced tumours. In each experiment a protective effect was claimed, but lack of published details of the exact experimental circumstances makes some of these claims difficult to evaluate. If the reported²⁸ protective effects of dietary β -carotene against tumour induction by transplanted cells or viruses are confirmed, this may merely reflect the reported^{22,23} enhancement of certain immune parameters by dietary β -carotene, the relevance of which to human cancer remains uncertain.

If the reported protective effects of systemic β -carotene against chemically induced skin cancers^{27,29} are confirmed (and are not trivially attributable to physical changes in the skin) this would be of more interest than protection by systemic β -carotene against skin cancer induction by UV light^{26,27}, for the latter may at least in part reflect a photoprotective rather than an anticancer effect. Further studies in all these areas will be needed before any general protective effects of β -carotene in experimental animals can be accepted. (No excess of tumours was reported in the chronic toxicity test of β -carotene³⁰, but details were not provided.)

Epidemiology

The foregoing laboratory evidence has been introduced not because it proves that β -carotene will have an anticancer effect, but chiefly as background material to aid interpretation of the epidemiological observation that people with above average blood retinol levels or above average β -carotene intake rates are at below average risk of cancer. Although the available epidemiological data (see below) indicate that both factors are associated with low cancer risk, this does not constitute overwhelming evidence for any real protective effect, for the differences are not great. A moderate relative risk (for example, a twofold difference in cancer risk between the bottom third and the top third of some population with respect to carrier-bound retinol in the blood or β -carotene in the diet) might reflect a

truly protective effect, but it might arise indirectly merely because carrier-bound retinol levels are correlated with some other factor that is a real determinant of cancer risk. Even more plausibly, perhaps people who like to eat a lot of vegetables get both β -carotene and some truly protective factor from them, or tend to avoid some real cause of cancer in meat or other foodstuffs of which they consume less. These difficulties of interpretation can be reduced by seeking epidemiological evidence for a protective effect in many different studies in different types of population but, even if there is a medically significant but numerically moderate protective effect of dietary β -carotene, and even if these epidemiological studies nearly all estimate it reasonably accurately, we may still not be sure that they have done so unless the effect can be reproduced experimentally in randomly controlled prospective intervention studies among humans.

Blood retinol and cancer avoidance

The differences between total retinol and carrier-bound retinol concentrations in human blood are often smaller than the random error of measurement in blood retinol estimation, and so we shall not distinguish carefully between them in some of what follows.

In general, because of the wide range of blood levels of retinol in countries where vitamin A deficiency is common, any true protective effect may show up most strikingly in malnourished populations. However, the relevance of carrier-bound retinol and of β -carotene can be assessed independently only in well-nourished populations where variation in β -carotene intake has little effect on carrier-bound retinol levels and so the blood levels of the two factors are largely uncorrelated.

Prospective serum studies: Retinol can be reasonably stable in stored blood samples, and two studies^{31,32} have analysed the total retinol levels in stored samples of blood taken some years previously for unrelated research purposes from American and British people who were apparently free of cancer at that time. In both studies, people with total blood retinol levels near the top of the normal range were at significantly lower risk of developing cancer over the subsequent few years than those with levels near the bottom of the normal range (Table 1). But, although the apparent protective effects are statistically significant, so few cancers were observed that there is substantial statistical uncertainty in the magnitude of the effect. (Anyone who has been sitting for a few years on a few thousand blood samples might consider matching them up with the local cancer registry or with official death statistics, as long as it is still possible to measure the retinol and, ideally, the RBP and β -carotene in them.)

Against this, one preliminary observation which, if confirmed, suggests that retinol is not importantly protective relates to oral contraceptive (OC) use. OC users have substantially elevated levels of blood retinol^{14,15}, but the aggregated evidence from three studies of OC use in relation to the onset of various diseases, including all cancers, does not suggest that any material reduction in cancer risk is associated with 5-9 or even 10-14 years of continuous use of OCs. Tumours of the breast, endocrine, reproductive and genital organs are excluded (as these are likely to be directly dependent on hormonal factors or on sexual activity) and smoking habits are standardized for (since OC users tend to smoke more than non-users). A non-significant deficit of remaining tumour onsets among OC users in the Oxford (M. P. Vessey, personal communication and ref. 82) and Royal College of General Practitioners (C. R. Kay, personal communication and ref. 83) studies of a total of 60,000 women is counterbalanced by an apparent excess of skin cancer onsets among OC users in the American Nurses Health Study of 120,000 women (F. E. Speizer, personal communication; unfortunately, these American data could not be corrected for any hypothetical biases due to a correlation of sunbathing with OC use). Lack of any protective effect among long-term OC users would be quite strong evidence that blood retinol is not importantly protective, unless the rise in blood retinol among

Table 2 Case/control studies of blood retinol or β -carotene

Country	Mean values (mg l ⁻¹)		Substance	No. and site(s) of cancers
	cases	controls		
India ³³	0.31	0.48	Retinol	555 oral
India ³³	0.68	0.85	β -carotene	555 oral
Pakistan ³⁴	0.22	0.40	Retinol	203 oral

* 'Carotene significantly lower' (in cases than in controls), but quantitative information not provided.

† Analytical methods not specified.

OC users is somehow due to a decrease in the ease with which peripheral cells can utilize retinol (or is in some other way compensatory).

Further large prospective studies of blood retinol are still needed. If they confirm the inverse association with cancer risks then identification of various intrinsic or extrinsic determinants of blood retinol will be necessary before it can be decided whether retinol *per se* is protective. Ideally, one might manipulate the determinants of blood retinol in a large randomized trial of cancer prevention, but as this may be impracticable (depending on the nature of these determinants) even uncontrolled observation, as in the above three studies of OC users, may provide useful clues.

Retrospective serum studies: Comparison of the total blood retinol levels of recently diagnosed cancer patients with the total blood retinol levels of control patients is easier and quicker than a prospective cohort study. Of the nine studies in India³³, Pakistan³⁴, East Africa³⁵, Britain³⁶⁻³⁹, or the United States^{40,41}, the eight which had at least a small control group³³⁻⁴⁰ all reported lower total retinol levels in cases than in controls (Table 2: all but one³⁶ of these eight are significant).

It may be relevant to the succeeding section to note that blood levels of β -carotene were also measured in some of these case/control studies. Among Indian, Pakistani and East African cases blood β -carotene levels were significantly lower than in controls. Unfortunately, β -carotene was measured in only three of the Western studies³⁸⁻⁴⁰, in each of which it was also somewhat lower in cases than in controls, even though no particular correlation between blood retinol and blood β -carotene levels need exist in developed countries.

The evidence provided by these eight case/control studies for either inverse association existing is not reliable, however, for in some studies there is no guarantee that the controls were appropriate and in all the studies the results might have been biased by a (hypothetical) 'nuisance effect' of depression of β -carotene or carrier-bound retinol by large, established cancers. There is still a need for large case/control studies in both developed and malnourished countries of carrier-bound retinol (and β -carotene) levels in people with small tumours that are unlikely to have had any material effect on diet or general metabolism (or in people who have been cured of malignant tumours some time previously with no obvious permanent damage to their digestive system or metabolism).

Dietary β -carotene and cancer avoidance

Turning from the blood to the diet, and shifting our emphasis from retinoids to carotenoids, a variety of independent epidemiological investigations have, in recent years, reported that cancer risks are inversely related to consumption of 'vitamin A'. This term embraces both retinol and the provitamin A carotenoids; but the total amount of 'vitamin A' in human diets from β -carotene (plus other carotenoids) often exceeds that from retinol.

In many cultures one particular plant or group of plants accounts for the majority of the dietary β -carotene: for example, carrots in North America⁴², yellow-green vegetables in Japan⁴³, red palm oil in West Africa⁴⁴ and dark green leafy vegetables among Singapore Chinese⁴⁵. Many epidemiological studies have investigated the relationship between β -carotene and cancer almost by accident, because dietary questionnaires designed for more general purposes happened to ask about the main local β -carotene source and it was realized only later that the lower cancer risks found among users of this particular foodstuff might be due to its β -carotene content. The correlation between the average β -carotene intake rates of different individuals over the past few years and their intake as assessed by such questionnaires cannot be high. So, if the observed 1.5- or two-fold relative risks (RR) of cancer typically observed when comparing low and high β -carotene intake groups (as assessed by dietary questionnaires) are indeed due to the β -carotene intake, the relative risk comparing true low with true high intake must presumably be somewhat more than

twofold, and might in principle be substantially greater. The results of these studies (5 prospective and 15 retrospective) are summarized in Table 3, and discussed below.

Prospective dietary questionnaires: All the Japanese in certain administrative areas were asked⁴³ to complete an extensive dietary questionnaire in 1965, and 265,118 did so. Over the next decade 807 died of lung cancer, yielding an age/sex/smoking-standardized relative risk of 1.4 ($P < 0.01$) for those who ate vegetables containing more than 1,000 IU of β -carotene per 100 g 'less than daily' with those who ate them 'daily'. Significant negative associations with daily use of these vegetables were also reported for stomach and prostate cancer, but the findings for other cancers were not reported. These yellow-green vegetables account for more than half of the β -carotene in the Japanese diet.

8,278 Norwegian men who had replied to postal questionnaires about both smoking (in 1964) and diet (in 1967) were followed for 5 years⁴⁶. A 'vitamin A index' (chiefly, in fact, a β -carotene index, since it included carrots and green vegetables but not liver or vitamin pills) was devised, low values of which were predictive of lung cancer incidence ($RR = 3$ for people in the bottom third of the population with respect to the 'vitamin A index' compared with people of similar age, sex and smoking habits in the top two-thirds; $P = 0.01$, but based on only 36 cases). A total of some 40,000 people completed the same questionnaire in 1966-67 in Norway or Minnesota⁴⁷, and the 10-year follow-up of these is being analysed, with apparently promising results (E. Bjelke, personal communication).

No other large prospective studies of either dietary β -carotene or preformed vitamin A have been published. It would be helpful if anyone who can link dietary questionnaires administered for any reason some years ago to subsequent cancer mortality (or, preferably, incidence) would do so, if they have reasonable estimates of consumption of at least the one or two main local β -carotene-containing plants plus at least 100,000 person-years of follow-up. For example, in Finland the detailed dietary questionnaires administered by the Research Institute for Social Security during 1966-72 to a geographically defined sample of 20,000 adults could be linked to the few hundred subsequent cancer onsets. Likewise, the Japan-Hawaii cancer project has by now sufficient data to provide some useful prospective information, although in Hawaii, as in Japan⁴³, one must interpret with particular caution correlations between any dietary habit and any cancer if both are subject to substantial trends, for artefacts will arise if the more modern members of society are more affected by both trends than are the more conservative members. Finally, dietary questionnaires have been administered to various large populations for research into cardiovascular disease, or for nutritional research, and these too might be exploitable. (Preliminary analyses of the 19-year follow-up of 2,000 people in Chicago who completed a 28-day dietary diary in 1959 indicate an inverse association of total cancer risk with β -carotene intake but not with retinal intake: R. Shekelle, personal communication.)

Retrospective dietary questionnaires: These involve asking people with cancer ('cases') and people without cancer ('controls') what vegetables, vitamin pills, etc. they normally ate in previous years, from which can be estimated⁴⁸ the relative risk of cancer in people with low, as opposed to high, β -carotene intake (or retinol intake—a nonsignificantly lower risk has been reported among users of vitamin A pills^{49,50}). One general difficulty is that feeling ill or knowing they have cancer may cause people to describe their past diet somewhat differently from how they would have described it if they had been healthy controls. If this bias is not substantial, the enormous advantage of the retrospective method is that it is quick (you do not have to wait for 10 years to see who develops the disease) and much less work (one questionnaire per case plus one per control), which allows more patients with cancer to be studied with consequently less random error in the final relative risk estimation. Although simple statistical methods⁴⁸ exist for correcting for age, sex, smoking and any dietary confounding variables

before calculating a test for a trend in the relative risk of cancer with respect to β -carotene or retinol intake, unfortunately investigators have often failed to use them or have used them but have failed to test for a *trend*, on only 1 degree of freedom.

At Roswell Park Memorial Institute in the United States, a few thousand cancer patients and a few thousand controls completed dietary questionnaires during 1957–62. Milk and some but not all other dietary sources of retinol were assessed, and carrots and some other major sources of β -carotene were assessed. A 'vitamin A' estimate was constructed for each person, which chiefly reflected provitamin A (β -carotene) intake, since on average five-eighths came from carrots (as β -carotene) and some more came from other vegetable sources of β -carotene⁴². Subjects were then classified as high, middle or low with respect to this estimate. When the 292 lung cancer patients were compared with selected controls⁵¹, the age/sex/smoking-standardized cancer risks relative to the high intake group were 1.0, 1.5 (middle) or 1.7 (low), and a test of the published data for an age/sex/smoking-standardized trend yields $P < 0.001$. An IARC case/control study of 233 Singapore Chinese lung cancers⁴⁵ indicated a $P < 0.01$ twofold protective effect of eating twice or more per week 'dark green leafy vegetables' (for example, kale), which are a major source of β -carotene for these people, but a similar case/control study⁵⁰ of 104 British lung cancers indicated no protective effect ($RR = 1.0$) of dietary 'vitamin A'. Returning to Roswell Park, the 569 bladder⁴², 122 oesophagus⁵² and 421 larynx⁵³ cancer patients were compared with selected controls. In seven sub-groups of decreasing (largely pro-) vitamin A intake, the risks of bladder cancer relative to those of the highest intake group were 1.0, 1.2, 1.4, 1.2, 1.7, 1.9 and 2.1, and a test of these published data for a trend again yields $P < 0.001$. Among the 122 oesophageal cancer patients divided into three sub-groups by dietary β -carotene intake relative risks of 1.0, 1.6 and 1.9 were found ($P = 0.03$ for trend), while among the 421 male larynx cancer patients divided into four dietary sub-groups, relative risks of 1.0, 2.1, 1.9 and 3.0 were found ($P < 0.005$ for trend) after adjustment for age, tobacco and alcohol. (Similar adjustment of the data for 581 oral cancers is necessary before the twofold protective effect seen in an unadjusted analysis⁵⁴ can be interpreted.)

The Roswell Park questionnaires comprise the largest set of case/control data available anywhere, and it is to be hoped that a single analysis of all cancers separately and together in relation to all controls will eventually become available in which trends in relative risks with respect to fine subdivisions of β -carotene and perhaps of retinol intake will be tabulated and standardized for finer subdivisions of age and smoking than heretofore.

There are also several studies relating gastrointestinal (GI) cancer risks to low vegetable intake rates but in all of these it is possible that vegetable components other than β -carotene (or dietary components other than the vegetables) account for the apparent protective effects in the GI tract.

Case/control studies of GI cancer have been reported from Hawaii^{55,56} and Israel^{57,58}, but in neither case were analyses reported with respect to specific estimates of β -carotene or retinol intake. Recently, the Israeli data on 406 cases and 812 controls have been re-analysed⁵⁹ with respect to an estimate of total dietary β -carotene for each case and for each control based on separate replies about more than 200 foodstuffs. There was no significant correlation between the risk of GI cancer and the estimated daily dietary carotene intake here (or in preliminary analyses of the Roswell Park data on GI cancers: S. Graham, personal communication). The only other study of GI cancer which has sought but not found any apparent protective effect whatever is the IARC case/control study of oesophageal cancer in French males⁶⁰, where the mean β -carotene (and retinol) intake was the same for the 200 cases as for the controls. By contrast, the IARC studies on oesophageal cancer in Iran⁶¹ indicate that the high-incidence areas were characterized by a diet extremely poor in green vegetables, and the main dietary finding in the subsequent IARC case/control studies within

high-incidence villages of several dozen dietary variables was a systematic lack of fresh fruit and vegetables among the cases⁶², although specific estimates of β -carotene (and retinol) intake in cases and controls were not published.

At other GI sites four separate case/control studies have been reported⁴⁷ each of which shows an age/sex-standardized relative risk of cancer that was statistically significantly greater than unity in people whose 'vegetable index' was lower, as opposed to higher, than normal. (Note, however, that only two control series, one in Norway and one in the United States, were interviewed.) The findings in these studies were⁴⁷:

- | | | |
|--------------------|-------------------------|------------|
| (a) Norway, | 228 stomach cancers: | $RR = 1.7$ |
| (b) United States, | 83 stomach cancers: | $RR = 1.5$ |
| (c) Norway, | 278 colorectal cancers: | $RR = 1.4$ |
| (d) United States, | 373 colorectal cancers: | $RR = 1.4$ |

In Liverpool, UK⁶³, a 1.6-fold relative risk of GI cancer ($P < 0.01$) was found if green vegetables were eaten less than weekly. Among vegetarians⁶⁴, a nonsignificant twofold relative risk was likewise found for colorectal cancer in Seventh Day Adventists who eat green, leafy vegetables 'less than' compared with 'at least' weekly. In India, it is reported⁶⁵ that studies of vegetarian sects consistently reveal smaller GI cancer risks, but no supporting data or references are provided. (Studies relating β -carotene intake to cancer risks within vegetarian sects would be free of confounding by associations with meat consumption.) Finally, in case/control studies⁶⁶ in a total of 521 gastric cancer patients in four countries, a lower intake of fresh fruits and vegetables in cases than in controls is indicated in the discussion, but the control data are not given (nor is the percentage of the controls who themselves had some other form of cancer).

Future research directions

Laboratory research: Most epidemiologists are well aware that the human evidence thus far available (Tables 2, 3) falls short of proof that increasing the average β -carotene intake would be of any material benefit in rich countries (or even in poor ones). *A fortiori*, the foregoing epidemiological studies may fail to interest many laboratory research workers whose habit is to trust only striking differences in well-controlled experiments. However, the perfect may well be the enemy of the relevant, for the detailed understanding of mechanisms which is slowly emerging from laboratory investigations of a few particular chemical, viral or physical agents (for example, SV40, phorbol esters or 2-acetylaminofluorene) may be of little immediate value if few human cancers are in reality due to these particular agents. Although in the long term fundamental research into any area of cell biology may prove relevant to the prevention or treatment of cancer, progress towards important preventive measures may be more rapid if, in addition to fundamental research, laboratory workers take the inevitably inconclusive leads provided by epidemiologists reasonably seriously (and vice versa, of course), one ultimate aim of this collaboration being to specify a few promising hypotheses in sufficient detail to make practicable their randomized evaluation among several thousand apparently healthy people for 5 or 10 years. Several laboratory studies are now possible that would test the plausibility of the more obvious mechanisms whereby β -carotene might be beneficial.

First, and most obvious, is to repeat the animal experiments in which important anticancer effects of β -carotene have been reported^{26–29}. Mechanistically, it would be interesting to discover whether dietary (not topical) β -carotene, started some weeks after weak (not massive) initiation of animals with DNA-binding carcinogens, has any material inhibitory effects on the later stage(s) of carcinogenesis, especially in tissues where dietary β -carotene is known to accumulate⁶⁷ or to cause accumulation of retinol⁶⁷.

Second, does β -carotene itself have any of the many direct effects on cultured cells or tissues that retinoids have? Such effects are relatively quick to obtain and easy to seek, although a variety of cell culture conditions and β -carotene vehicles may

Table 3 Questionnaire studies of cancer in relation to intake of some β -carotene-rich vegetable(s), or of 'vitamin A'. Note that 'Vitamin A' was estimated from a limited range of dietary components, chief among which in most of these studies has been the β -carotene in certain vegetables

Country	Relative risks (lower: higher intake)	No. of cancers	Subdivision by
Norway ⁴⁶	2.6: 1	36 lung	'Vitamin A'
Norway ⁴⁷	1.7: 1	228 stomach	Vegetables
Norway ⁴⁷	1.4: 1	278 colorectal	Vegetables
Minnesota, USA ⁴⁷	1.5: 1	83 stomach	Vegetables
Minnesota, USA ⁴⁷	1.4: 1	373 colorectal	Vegetables

United Kingdom ⁵⁰	0.7*: 1.3: 1.4: 1.1: 1	104 lung	'Vitamin A'
Israel ⁵⁹	1.1: 1.1: 1	406 gastrointestinal	β -carotene†
France ⁶⁰	1.0: 1	200 oesophagus	β -carotene
United Kingdom ⁶³	1.7: 1.1: 1	514 gastrointestinal	Green vegetables
US vegetarians ⁶⁴	2.2: 0.9: 1	41 colon	Green vegetables
Iran ⁶²	1.7: 1	344 oesophagus	Raw vegetables
Japan ⁴³	1.3: 1	611 male lung	"green/yellow‡" vegetables
Japan ⁴³	1.5: 1	196 female lung	
Japan ⁴³	2.0: 1	63 prostate	
Japan ⁴³	1.1: 1	1823 stomach	

Note: In addition, a US prospective study in 1948–54 reported an inverse association (risk ratios 2.2:1.6:1) with all-causes mortality⁸⁴.

* Bottom quintile based on only seven cancers, and so unreliable.

† Relative risks estimated from simultaneous regression on both retinol and β -carotene intake.

‡ Defined as any which contained over 1,000 IU of carotene per 100 g.

have to be studied. The weak effects already reported⁶⁸ could be pursued.

Third, although much of the enzymic oxidation of β -carotene to retinal takes place in the intestine, is there sufficient oxidation at other sites in humans to provide an appreciable source of localized retinol, or some other substance with retinoid-like activity? Dioxygenase, the enzyme which can oxidize β -carotene to retinal, has been demonstrated chiefly in the intestine, but it is also present in the liver and, to a lesser extent, the kidneys⁴. In which human tissues can β -carotene be converted into retinol? (When mice are treated with β -carotene deposits of it accumulate in many tissues, and deposits of retinol also accumulate in the lung and skin⁶⁷.)

Fourth, β -carotene is among the most efficient substances known for quenching the excitation energy of singlet oxygen^{24,25,69} and also for trapping certain organic free radicals⁷⁰. It has been suggested that anticancer effects (albeit perhaps on only the 'early' stage(s) of carcinogenesis) may be produced by deactivation of these chemical species⁷¹ or by otherwise preventing the lipid peroxidation or other oxidative damage which they might cause^{72–75}. This suggestion could, of course, be tested if people with a deficient ability to 'quench' singlet oxygen or to 'trap' certain types of free radical could be identified and their cancer onset rates monitored. If either chemical species is relevant, can realistic physiological concentrations of β -carotene, or any other carotenoids, effect any material reduction in the amounts of lipid peroxidation or other cellular damage caused by free radicals or by unquenched singlet oxygen, and is such oxidative damage importantly involved in carcinogenesis?

Fifth, both in poor and in rich countries, what are the chief dietary and other determinants of the differences that now exist between the blood levels of carrier-bound retinol and of β -carotene in different people? To what extent, for example, do they depend on dietary β -carotene, intestine-derived retinol, other micronutrients, or hormonal status? Comparing poor countries with each other⁷⁶, there is a correlation between dietary (pro-) vitamin A and blood retinol; but, as one would expect, the relationship seems to reach a maximum and then flatten off. Both oral contraceptives and pregnancy strongly affect blood retinol levels^{14,15}; what of menarche, menopause and dietary or medicinal hormones? Finally, diseases of the kidney¹⁶, thyroid^{5,16} and pancreas⁷ have been reported to cause increases or decreases in blood retinol or β -carotene; how do

they do so, and which other diseases (especially of hormone-secreting tissues) do so?

This list of laboratory questions could doubtless be extended. The general point is that the evidence linking β -carotene intake to cancer risk in man is already sufficiently consistent for laboratory workers to start to seek plausible explanations for it, bearing in mind the superficially paradoxical fact that dietary β -carotene may not affect serum retinol very much in developed countries.

Observational epidemiology: There are some populations (notably in parts of West Africa and Brazil) within which β -carotene intake varies enormously, due to the use of red palm oil. If β -carotene is really protective this wide variation should produce quite a striking variation in the relative risk of cancer, and so the Imperial Cancer Research Fund are supporting a case/control study (with J.D.B. and Dr. A. Kalache) in a part of Brazil where red palm oil is used by some, but not by all. Apart from this, and a general refining of questionnaires and statistical analyses to pick out the separate effects of β -carotene and retinol more specifically, we need more rigorous serum epidemiology to investigate the predictive value of serum retinol and β -carotene retrospectively or, preferably, prospectively. (Repeat measurements of retinol and β -carotene a year or more apart on a number of individuals to estimate within-person and between-person variability is a prerequisite for proper interpretation of such studies.) Future serum-based case/control studies are needed both in developed countries and in populations where hypovitaminosis A is endemic, but these should be large and should exclude artefactual effects of established tumours on blood levels (via effects on recent appetite or on general metabolism), perhaps by restricting interest to pre-cancerous lesions, to small non-digestive organ tumours, or to small tumours which have been cured without much trauma a year or more previously. Better, however, would be truly prospective studies, either starting *de novo* or utilizing blood samples taken years ago for other purposes but stored in conditions that still allow estimation of retinol and, ideally, β -carotene. Also, the question of whether prolonged oral contraceptive use reduces cancer risks should be pursued, as this may help determine whether any inverse association between blood retinol and cancer is due to a true protective effect of blood retinol, or merely to a secondary association (in which case, with what?). Likewise, any other extrinsic or intrinsic determinants of blood

retinol deserve epidemiological study. Finally, to help elucidate mechanisms, cancer onset rates might be monitored among small populations (if these can be found) with chronic metabolic defects which markedly elevate or depress blood levels of unbound retinol, carrier-bound retinol or β -carotene, or among people deficient in the β -carotene-oxidizing enzyme dioxygenase, in some of the normal mechanisms for quenching singlet oxygen, or in the enzymes for recognizing or utilizing retinol in peripheral tissues.

Intervention studies: In view of the general association previously observed between low vegetable use and cancer risks, it must be assumed that future, perhaps more specific, observational studies of serum β -carotene and retinol levels are in aggregate likely to continue to yield some inverse association with cancer risks, although the magnitude of the relative risk that will emerge cannot be predicted. If it is large then a clear need for randomized intervention studies will arise, but even if it is only moderate there will be no reliable way other than by randomized intervention to decide whether it reflects a cause-and-effect relationship. However, although analogy with the effects of giving up smoking suggests that inhibition of the late stages of human neoplastic progression should yield measurable effects within about 5 years, there may be little benefit apparent during the first 2 or 3 years of such a trial. Consequently, if randomized intervention trials are eventually to be undertaken then the sooner they are started the better, as long as they test β -carotene (preferably at as high a daily dose as possible without significant skin yellowing) rather than retinol, in the hope of detecting either any benefits of intestine-derived retinol or any direct benefits from circulating or adipose tissue β -carotene.

Testing β -carotene has the advantage of avoiding the risk of hypervitaminosis A arising among a few subjects who choose to overdose themselves⁵, for 'as far as is known hypercarotenosis in all its forms is entirely harmless'⁹ (and there is no evidence that the one man reputed to have died of carrot juice actually did so⁷⁷). Indeed, the joint FAO/WHO Expert Committee on Food Additives⁷⁸ formally estimated the acceptable daily intake of β -carotene for a 70 kg adult to be 350 mg per day! Since the normal range of human intake of this biologically active substance is only a few mg per day, this committee showed a remarkable faith in their ability to extrapolate from apparently complete safety in a few rats to safe levels in large human populations, but amounts of one or two hundred mg per day are regularly prescribed for the treatment of erythropoietic protoporphyria without causing hypervitaminosis A, liver dysfunction or any other apparent ill effect^{8,79-81} and large amounts are also consumed by many West Africans and Brazilians who prepare food with red palm oil. (Ghanaian liver retinol and blood carotene levels are grossly elevated, but their median blood retinol is normal⁴⁴.)

Long-term randomized intervention studies with β -carotene might be worthwhile on almost any category of persons at high enough risk of cancer for several dozen occurrences, recurrences or progressions to be anticipated in a practicable sized study group within a few years. However, among really high-risk people trials of synthetic retinoids may be preferred, despite the possibility of toxic effects. With β -carotene, perhaps the most interesting possibility is randomized intervention in the general population, or in those of the general population who seem to have less retinol or β -carotene than average by dietary questionnaires or by serum analysis. It may be most practical in such studies to restrict interest to people over 50 or over 60 years old, because in younger people (even if they smoke, which merely doubles their age-specific cancer risk) the cancer onset rate is so low that impractically large numbers would be needed to characterize the moderate benefits that might realistically be hoped for. Even if there is a really worthwhile benefit from β -carotene, it may require 5 years of study of many thousands of people aged over 50 years before clear evidence of benefit emerges, so that complicated follow-up and any other source of organizational complexity will have to be avoided if such trials are to be maintained for several years.

Conclusion

Blood retinol: In malnourished populations, increasing the dietary intake of β -carotene or retinol among people deficient in vitamin A can rectify the deficiency and cause blood retinol levels to rise, a procedure of such obvious medical value that it matters little from a public health point of view whether it also diminishes cancer incidence. Although this may likewise hold for that small minority of people in developed countries whose diet is seriously deficient in vitamin A, for most people in developed countries neither dietary β -carotene ('provitamin A') nor dietary retinol ('preformed vitamin A') have much effect on blood retinol. If the inverse association between blood retinol and cancer incidence that has recently been reported from small prospective studies in developed countries is confirmed in larger prospective studies it may well reflect a true cause-and-effect relationship. Even if it does, however, this will not suggest that increasing dietary vitamin A or provitamin A will reduce cancer incidence in a developed country for they have little effect on blood retinol. Rather it would suggest that the hormonal and other extrinsic factors which do influence blood retinol levels need to be discovered, and that when they have been the effects on total health of manipulating them will need to be evaluated rigorously in long-term trials.

β -carotene: When dietary β -carotene rather than blood retinol is considered, it appears that so many observational studies of dietary factors and cancer incidence have already indicated a slightly lower than average incidence of cancer among people with an above average intake of β -carotene that it is most unlikely that this association will disappear entirely with future observational studies, whether of blood or of dietary β -carotene. This inverse association may, of course, be an artefact, due merely to association of β -carotene ingestion with some truly protective dietary habit(s) or component(s), or to association of β -carotene ingestion with avoidance of some truly harmful dietary habit(s) or component(s). Equally, however, the inverse association between dietary β -carotene and cancer incidence may be due to a genuine protective effect of β -carotene against the onset of cancer. If so, perhaps it is the β -carotene that is absorbed unchanged from the intestine which is chiefly responsible for this protective effect rather than any retinol or retinal generated in the intestine from β -carotene, in which case this protective effect could not be produced by dietary retinol alone. Although various lines of laboratory and field research can be envisaged which might tip the balance of probability a little one way or the other as to whether β -carotene is or is not truly protective, it seems unlikely that this question will be decided unequivocally in the foreseeable future unless controlled trials are undertaken. Although the evidence thus far available is not compelling that β -carotene is truly protective against cancer (or, *a fortiori*, against total mortality) this is not a good reason to delay starting controlled trials because even if, as seems probable, a few truly protective agents do await discovery among the dozen or two dietary factors of current interest to the research community, compelling evidence may take decades to emerge without controlled trials.

Preventive measures, especially those which may be relevant over a long period to many millions of people, deserve peculiarly rigorous evaluation. Apart from reducing the amount consumed (or harmfulness) of tobacco, there are few lines of research or governmental action that offer any medium-term hope of achieving substantial reductions in total cancer incidence rates. Seeking extrinsic determinants of the blood levels of carrier-bound retinol is one, and investigating the anticancer effects of the carotenoids is another. In each case, whether or not a fruitful outcome is thought to be probable, the fact that it is at least plausible would justify pursuit of some of the suggested lines of research.

We thank Bruce Ames for suggesting the relevance of singlet oxygen and John Cairns for suggesting how to test this, Professor Saxon Graham and his co-workers Curtis Mettlin and Jim Marshall, Dr M. Mathews-Roth, Dr E. Bjelke, Dr R. Shekelle,

Dr R. Willson, Dr H. Cuckle, Professor B. Modan, Professor M. P. Vessey, Dr C. R. Kay and Dr F. E. Speizer, for permission to mention their unpublished results, and Mrs V. M. Godwin for repeatedly preparing the typescript.

ARTICLES

Earth's neodymium budget and structure and evolution of the mantle

Geoffrey F. Davies

Department of Earth and Planetary Sciences, McDonnell Center for the Space Sciences, Washington University, St Louis, Missouri 63130, USA

Neodymium and strontium isotopic data from rocks can be satisfied by a model in which the mantle contains chemical heterogeneities of many sizes which are less depleted in incompatible elements than the surrounding mantle, and in which the entire mantle is slowly mixed by convection.

NEODYMIUM isotopic abundance data have been used to constrain models of the structure and evolution of the Earth's mantle^{1–5}. According to some studies, only a fraction (one-third to one-half^{1,3–5}) of the mantle has been differentiated to form the continental crust, and the rest of the mantle is thought to retain its primitive Nd isotopic composition. This would favour models in which the mantle is compositionally layered, but not those in which the mantle is mixed on the large scale by whole-mantle convection. As our ideas on the evolution of the Earth will be strongly affected by which model is correct (geophysical constraints having proved inconclusive^{6–11}) so we need to establish the uncertainties of the isotopic constraints and the interpretations. Unfortunately, recent studies have only briefly considered the uncertainties of the constraints, they have assumed that only layered mantle models are viable, and the

complexities of calculations of the evolution of these models have obscured their sensitivity to uncertainties in the data.

This article examines the uncertainties of the Nd isotopic constraints; this is simplified by considering the present Nd budget of the Earth separately from the evolution of the Earth and of Nd. The mass of mantle which has been depleted to form the continental crust is found to be uncertain, and identifying this with the seismologically defined upper mantle is premature.

Some deficiencies of layered mantle models are also pointed out—the narrow range of Nd isotope data for ocean island basalts is not explained, and an important part of the rationale for layered models may be undermined by recent Nd data for kimberlite inclusions.

A model with a heterogeneous mantle and whole-mantle convection is proposed. It is pointed out that whole-mantle

Fig. 1 Nd-Sr isotopic correlation for some oceanic rocks and kimberlite inclusions. Mid-ocean ridge basalt (MORB, ●) and oceanic island basalt (OIB, ○) data from ref. 2. Kimberlite inclusion (KI, ■) data from ref. 22. $\epsilon_{Nd} = 10^4(\alpha_{Nd}/0.511836 - 1)$ (refs 4, 12, 13). $\epsilon_{Sr} = 10^4(\alpha_{Sr}/0.7045 - 1)$ (refs 12, 14), where $\alpha_{Sr} = {}^{87}\text{Sr}/{}^{86}\text{Sr}$.

convection involves long overturn times and very long residence times, that plate tectonics must continuously generate heterogeneities, and that both mechanical and thermochemical factors may extend the survival times of heterogeneities to thousands of millions of years.

Nd isotope data

Variations in $\alpha_{Nd} = {}^{143}\text{Nd}/{}^{144}\text{Nd}$ produced by the decay of ${}^{147}\text{Sm}$ are conveniently measured in terms of ϵ_{Nd} (ref. 12), which measures parts in 10^4 deviations of α_{Nd} from a reference value that is based on measurements of the Juvinas meteorite¹³, and is assumed to represent an average chondritic value. Mid-ocean ridge basalts (MORB) have ϵ_{Nd} values near 10 (refs 12, 14–16), indicating that the MORB source (the oceanic mantle) is depleted in large-ion lithophile (LIL) elements relative to chondrites. Conversely, many young continental rocks have negative ϵ_{Nd} values^{17–20} indicating a complementary LIL-enrichment relative to chondrites. Island arc rocks tend to have $\epsilon_{Nd} \sim 8$, while oceanic island basalts (OIB) tend to have $\epsilon_{Nd} \sim 6$, but with some ranging to near zero^{2,12,14,16}. Continental flood basalts (CFB) tend to have ϵ_{Nd} values near zero²¹, which suggests they derive from a source which is primitive and chondritic^{1,4}. A negative correlation between ϵ_{Nd} and ϵ_{Sr} has been found for oceanic rocks^{12,14–16}, where ϵ_{Sr} is the analogous measure of the Rb-Sr system¹² with $\epsilon_{Sr} = 0$ being defined by the point where the correlation crosses $\epsilon_{Nd} = 0$. This correlation is shown in Fig. 1 for a selection of MORB and OIB samples². Recently some kimberlite inclusion (KI) data have been obtained which extend this correlation through the origin²² (Fig. 1). Other continental rocks and island arc rocks often deviate from this correlation, and this can often be attributed to contamination by seawater or lower continental rocks of magma originally lying on the correlation line^{17,20,23–25}.

Nd in chondrites

Interpretations of the above data have been based on the assumptions that the average crust-mantle system (bulk Earth or BE) has chondritic Sm/Nd and Rb/Sr ratios, and that chondritic material will have $\epsilon_{Nd} = 0$. The first assumption is very difficult to justify with any rigour. For example, if chondrites derive from a relatively small number of parent bodies, then our sample may be significantly biased. Furthermore, the Earth may have sampled a slightly different population of material, because

many meteorites are believed to be derived from the asteroid belt, more than twice as far from the Sun as the Earth.

There are some limited data with which the second assumption has been tested. Jacobsen and Wasserburg²⁶ have reported Sm and Nd isotopic and abundance data for several chondrites and achondrites (including Juvinas). Their results imply $\epsilon_{Nd} = -1 \pm 1$ at present and $\epsilon_{Nd} = -2 \pm 0.5$ at 4,500 Myr ago, but it is not clear to what extent these discrepancies from $\epsilon_{Nd} = 0$ may be due to interlaboratory biases^{26,27}. (Note that these ϵ values are based on the old reference values^{12,13}, and not on the new ones defined by Jacobsen and Wasserburg²⁶.) About 50 isotope dilution measurements of Sm/Nd in chondrites^{28–32} give a mean ${}^{147}\text{Sm}/{}^{144}\text{Nd}$ of 0.196 ± 0.002 (see also refs 26, 27), compared with the Juvinas reference value of 0.1936 (ref. 13). If all chondritic material began with $\epsilon_{Nd} = 0$, this Sm/Nd range would generate a range of 2 ± 6 (1 s.d.) in ϵ_{Nd} , with the mean being $\epsilon_{Nd} = 2 \pm 2$ (2 s.d.).

Present Nd mass balance

Suppose that the mantle initially had mass M , Nd mass concentration C_0 and $\epsilon_{Nd} = \epsilon_0$. Suppose that later the mantle comprises several reservoirs with masses M_i , concentrations C_i and $\epsilon_{Nd} = \epsilon_i$, and the mass fraction $x_i = M_i/M$. Then the equations which express conservation of the masses of the mantle and Nd and the total amount of radiogenic Nd produced in the interval are

$$\begin{aligned} \sum x_i &= 1 \\ \sum x_i C_i &= C_0 \\ \sum x_i C_i \epsilon_i &= C_0 \epsilon_0 \end{aligned} \quad (1)$$

Fig. 2 Models of ϵ_{Sr} and ϵ_{Nd} evolution calculated from equation (1) and its Sr analogue ($Q_{Sr} = 0.0167 \text{ Myr}^{-1}$, ref. 4). *a*, Evolution of ϵ_{Sr} in the oceanic mantle (OM) relative to the bulk Earth (BE). OM lines are labelled with the Rb-Sr enrichment factor, f_{Sr} . Error bar on BE is the estimated uncertainty of the present BE value of ϵ_{Sr} (see text). $f_{Sr} = (\mu_{Sr}/0.0839 - 1)$, where $\mu_{Sr} = {}^{87}\text{Rb}/{}^{86}\text{Sr}$ (refs 4, 12, 14). *b*, Evolution of ϵ_{Nd} for oceanic mantle (OM), continental mantle (CM) and continental crust (CC) for mean differentiation ages of 1,800 and 2,500 Myr. Lines are labelled with values of f_{Nd} .

Fig. 3 Alternative explanations of the correlation in Fig. 2. *a*, Depleted (D) and primitive (P) sources evolve independently from 0. Mixing from D and P then yields the isotopic composition X. The presence of an enriched source (E), as suggested by kimberlite inclusion data²², implies that either E evolved independently of but colinearly with D and P, or that P results from mixing of D and E and is therefore not primitive. Straight mixing lines require the sources to have the same Sr/Nd ratio⁴⁶. *b*, All sources evolve independently but colinearly. This requires coherent fractionation of Sm/Nd and Rb/Sr: specifically, that sources have the same ratio of enrichment factors, f_{Nd}/f_{Sr} (refs 2, 53).

These relations are implicit in the treatments of Nd evolution and partitioning by O'Nions *et al.*³ and Jacobsen and Wasserburg⁴, but they did not separate the instantaneous mass balance from the evolution. In equations (1), the evolution is implicit in the present values of ϵ .

Some results of applying equations (1) are given in Table 1. Cases 1–4 are variations on Model 1 of Jacobsen and Wasserburg⁴ (which is similar to Case 3, Table 1): the present reservoirs considered are the continental crust (CC), depleted mantle (DM), and primitive mantle (the same as the initial mantle, but with a smaller mass). The parameters of the initial mantle (IM) and of CC were assumed, and those of DM were calculated, assuming $\epsilon_{DM} = 10$, consistent with Fig. 1 (ref. 4). The initial concentration of Nd, $C_0 = 0.9 \mu\text{g per g}$, is lower than that assumed by Jacobsen and Wasserburg⁴, and is based on thermal evolution models of the Earth^{33,34} which require uranium abundances in the mantle to be ~ 1.5 times chondritic: C_0 is also assumed to be 1.5 times chondritic, rather than twice chondritic⁴.

Case 1, Table 1, requires about half of the mantle to have been depleted ($x_{DM} = 0.48$). If ϵ_{CC} is assumed to be -30 rather than -20 , which implies an older crust, then about two-thirds of the mantle must have been depleted (Case 2). On the other hand, if $C_0 = 1.26 \mu\text{g per g}$ (ref. 4), then only one-third of the mantle need have been depleted (Case 3). The sensitivity of the mass

balance to ϵ_0 is illustrated by Case 4: almost the entire mantle must have been depleted if ϵ_0 is increased to $+4$.

There is increasing evidence that the sub-continental mantle is veined by LIL-element-enriched phases which were emplaced by metasomatic events into previously depleted mantle^{23,35–37}. The kimberlite-inclusion data in Fig. 1 suggest that $\epsilon_{Nd} = -10$ may be reasonably representative of this heterogeneous material. Its total abundance is difficult to estimate, but one constraint may come from continental heat flow data, from which it is inferred that $\sim 25 \text{ mW m}^{-2}$ of heat flux comes from below the upper 10–15 km of the crust³⁸: this is compatible with uranium and thorium abundances in the continental lithosphere up to ~ 10 times chondritic abundances (that is, U abundances up to $\sim 0.15 \mu\text{g per g}$). Jordan³⁹ points out that continental garnet lherzolite inclusions have K and other LIL abundances compatible with this degree of enrichment, and he summarizes the confluence of geophysical and geological data favouring the existence of an ancient, stable, LIL-enriched subcontinental mantle. Thus the subcontinental mantle may be an ancient reservoir with significant Sm and Nd enrichments.

Cases 5–8 of Table 1 explore the possible effect of an additional reservoir in the sub-continental lithospheric mantle (CM) by giving the Nd concentration in CM which would be required by depletion of the entire remaining mantle ($x_{CM} = 0.03$ corresponds to continental lithosphere $\sim 200 \text{ km}$ thick). Cases 5, 6 and 8 yield abundances from ~ 3 – 13 times chondritic ($0.6 \mu\text{g per g}$); only Case 7 clearly violates the constraint inferred from heat flow.

These results demonstrate that the fraction of mantle which has remained undepleted is subject to large uncertainties. Thus, the identification of the undepleted mantle with the lower mantle is speculative, and most of the mantle may possibly have been depleted.

Age of the continental crust

Because of the long half life of ^{147}Sm , ϵ_{Nd} varies approximately linearly with time in a closed Sm–Nd system, and can be written⁴:

$$\epsilon_{Nd}(t) = \epsilon_{Nd}(0) + Q_{Nd}f_{Nd}t \quad (2)$$

where $Q_{Nd} = 0.02474 \text{ Myr}^{-1}$ is a constant related to the decay constant, t is time and f_{Nd} is the Sm–Nd enrichment factor of the reservoir relative to Juvinas: $f_{Nd} = (\mu_{Nd}/0.1936 - 1)$ and $\mu_{Nd} = ^{147}\text{Sm}/^{144}\text{Nd}$. Jacobsen and Wasserburg⁴ have shown that equation (2) yields an upper bound, T , on the mean age of a reservoir if $\epsilon(-T)$, $\epsilon(0)$ and f_{Nd} are known.

The chronology of the continental crust is a major question in the mass-balance calculations (and in Earth history in general). Equation (2) shows explicitly how the evolution of reservoirs enters the mass balance calculations of the previous section. For example, Case 2 (Table 1), with $\epsilon_{CC} = -30$, would require the continental crust to be older, or to have a more negative f_{Nd} , or both, than Case 1, with $\epsilon_{CC} = -20$.

Table 1 Nd mass balance

Case	Initial mantle ($x = 1$) C ($\mu\text{g per g}$)	ϵ	x	Depleted mantle ($\epsilon = 10$) C ($\mu\text{g per g}$)	Continental crust ($x = 0.0055$, $C = 26$) ϵ	Continental mantle ($x = 0.03$, $\epsilon = -10$) C ($\mu\text{g per g}$)
1	0.9	0	0.48	0.60	-20	—
2	0.9	0	0.64	0.68	-30	—
3	1.26	0	0.34	0.84	-20	—

8	0.9	4	0.97*	0.71	-20	1.6

* Assumed.

Fig. 4 Some aspects of the heterogeneous mantle models. Blobs represent chemical heterogeneities which are less LIL-depleted than the surrounding mantle. Heterogeneities are of many sizes, but their geometry is unknown; they may be generated at subduction zones and higher concentrations of radioactive heat sources would make them prone to diapirism; they would tend to be destroyed or dispersed by the shearing of convective flow.

Jacobsen and Wasserburg⁴ estimated the mean age of the crust-mantle differentiation using the Rb-Sr system in the oceanic mantle (OM). For OM, the present ϵ_{Sr} is about -27 (Fig. 1), and they estimate that f_{Sr} lies between -0.8 and -0.95, with -0.9 being their preferred value. The mean age, T_{Sr} , of OM can then be obtained from the Sr analogue of equation (2), and the graphical solution is shown in Fig. 2a: assuming that initially OM had $\epsilon_{Sr} = 0$, the result is $T_{Sr} \leq 1,800$ Myr. This is a rather small age for the depleted OM and its complementary continental crust (CC), and would favour Cases 1 and 3 ($\epsilon_{Nd} = -20$) rather than Case 2 ($\epsilon_{Nd} = -30$), as is shown in Fig. 2b assuming that $f_{Nd} = -0.4$ for CC⁴.

Jacobsen and Wasserburg's^{4,40} confidence in this estimate is based on the presumption that the OM is strongly depleted in Rb, so that f_{Sr} must be close to -1 and its absolute uncertainty cannot be large. However, Weaver and Tarney⁴¹, for example, estimate $f_{Sr} = -0.73$ for OM, which yields $T_{Sr} \leq 2,200$ Myr (Fig. 2a). Note that the bulk Earth value of ϵ_{Sr} is inferred from the correlation in Fig. 1 and is, therefore, uncertain by about ± 5 (and the correlation may not even preserve direct information about the initial ϵ_{Sr} of the Earth). When account is taken of such uncertainties in enrichment factors and ϵ values of various reservoirs^{3,4,41}, one must conclude that equation (2) and its Sr analogue do not yet give very strong constraints on the mean age of the crust-mantle differentiation (Fig. 2a).

On the other hand, the observations that the continents contain provinces which were stabilized by the late Archaean (~2,500 Myr ago), are of average crustal thickness (35-40 km) and which have little or no sediment cover lead to the conclusion that much of the continental crust had been differentiated by the late Archaean (see refs 42-44). Wise⁴² estimates that 90% of the continental crust had been differentiated by the end of the Archaean. This conclusion can be avoided if the Archaean crust had subsequently been thickened by underplating, but there is no recognized modern analogue of such a process, and it would have to be an extremely delicate process to affect broad areas uniformly without leaving recognizable effects at the surface. This conclusion would imply that the mean age of differentiation of the continental crust from the mantle is $\geq 2,500$ Myr.

If the mean age of the continental crust is as great as 2,500 Myr, and with estimates of f_{Nd} of CC ranging from -0.35 to -0.48 (refs 3, 4, 41, 45), then it is quite plausible for ϵ_{Nd} of CC to be -30, as assumed in Table 1. It follows that well over half of the mantle may be LIL-depleted. Note that a Sr mass balance may also be calculated^{3,4} as was done here for Nd, but the uncertainties for that calculation are at least as great: the mean Rb-Sr enrichment of the continental crust, in particular, is very uncertain.

The layered mantle model

Wasserburg and DePaolo¹ have advocated a two-reservoir mantle model in which the (seismologically defined) upper mantle is identified as depleted oceanic mantle and the lower mantle is identified as a primitive (chondritic) source of the continental flood basalts. This division is suggested by their mass balance estimates^{1,4} (see case 3, Table 1). In this model the correlation in the depleted quadrant of Fig. 1 comprising MORB, island arcs, OIB and CFB (not shown, but with $\epsilon_{Nd} \approx 0$), is interpreted as a mixing line between MORB and CFB. If that is true, then the clustering of the OIB data at $\epsilon_{Nd} = 6 \pm 2$ is puzzling: why do not all degrees of mixing occur? As no one seems to advocate a special intermediate source reservoir with $\epsilon_{Nd} = 6$, the clustering must be due either to the small data sample or to some unknown mechanism. If either of these is true for the OIB, then why not also for the CFB, clustering at $\epsilon_{Nd} = 0$, especially because the new KI data suggest that the correlation of Fig. 1 extends into the enriched quadrant?

There are two mechanisms which might yield a correlation like that in Fig. 1, and these are shown in Fig. 3: mixing between two reservoirs (Fig. 3a), and coherent fractionation with independent evolution of sources (Fig. 3b). As long as only two reservoirs were sufficient to account for the data, the mixing hypothesis was perhaps preferable. However, the advent of the KI data (Fig. 1) necessitates at least one more reservoir: an enriched KI endmember (E, Fig. 3). If these reservoirs have evolved independently and colinearly, then coherent fractionation is established and can be invoked for any other point on the correlation line. Alternatively, if all points between D and E result from mixing of D and E (requiring identical Sr/Nd (ref. 46)), then it would only be coincidence that the CFB have $\epsilon_{Nd} = 0$, the identification of the CFB source as primitive would be premature, and the primitive values of ϵ_{Sr} would be unknown. Furthermore, the geometry of the sources would have to be revised. In either case, the KI data make the case for the layered two-reservoir mantle model much less compelling.

Another important question about the layered mantle model is how the layers separate (note that the separation must not be complete, as lower mantle material is required to reach the surface). The mantle transition zone may effect this separation, either by the effects of phase changes or, more likely, by a change in intrinsic density⁶. If the upper mantle is separated in this way and has been steadily depleted, then, according to Jacobsen and Wasserburg⁴, the concentrations of some highly incompatible elements in crustal rocks would have decreased 10-fold in the past 3,500 Myr, and they claim there is no evidence for this. If, as they prefer, the depleted mantle has been steadily growing in volume, with a constant degree of depletion, then it would only be coincidence if its lower boundary coincided with the transition zone at present. If the boundary between depleted and undepleted layers does not coincide, or has not coincided, with the transition zone, then the existence of the boundary and its ability to prevent mixing become *ad hoc*: it is certainly possible, but there is no compelling geophysical evidence for another boundary in the mantle.

Heterogeneous mantle model

At this stage, the Nd data can be interpreted in terms of an alternative model of the mantle which is chemically heterogeneous up to the largest scales and in which the entire mantle is slowly mixed by convection. The geophysical evidence is equivocal on the question of the structure of mantle convection: both whole-mantle convection^{6,7,11} and convection in separate layers⁸⁻¹⁰ have been recently advocated on the basis of geophysical evidence, so geochemists must also consider these alternatives.

The type of model proposed is shown in Fig. 4. It is postulated that the average mantle is fairly strongly LIL-depleted ($\epsilon_{Nd} \approx +10$) and that a small volume fraction (perhaps 10-20%) comprises less depleted or enriched regions. These regions are depicted in Fig. 4 as blobs, but their geometry is unknown. They

could be remnants of primitive mantle ($\epsilon_{Nd} = 0$), but it is more likely that they are products of more complex differentiation histories involving both enrichments and depletions, resulting in a wider range of ϵ_{Nd} ($10 \geq \epsilon_{Nd} \geq -10$). If these differentiation events involved coherent fractionation, as at least some must have, according to the earlier discussion, then the linear array of Fig. 1 would result. The heterogeneities may range in size up to hundreds or even thousands of kilometres, as suggested by the largest oceanic volcanic hotspots (Iceland and Hawaii), and down to grain sizes³⁵⁻³⁷. The mantle heterogeneities must have existed through much of the Earth's history, as indicated by the mean age of the crust and mantle reservoirs (Fig. 2), and by inferred ancient metasomatic events²³.

Subduction zones must generate mantle heterogeneities, because subducting oceanic lithosphere is strongly stratified and it apparently remains mechanically coherent at least to depths of hundreds of kilometres. The upper mantle part of subducted lithosphere is presumably LIL-depleted and refractory: it may therefore be mechanically strong and persistent, while pieces of it may ultimately become incorporated into continental lithosphere^{39,47}. The crustal part is enriched in some LIL elements and hydrated⁴⁰; much of the enriched component may be incorporated into island arc magmas^{20,24,25}, but some probably escapes this process and returns to the mantle⁴³. Until the complexities of island arc geochemistry and of sialic crust generation are better understood, it is difficult to predict the character of such LIL mantle enrichments, but if they are significantly enriched in radioactive heat sources (U, Th, K), they would be prone to diapiric instability and uprising as mantle viscosity is a strong function of temperature. Such diapirs would be likely to mobilize and concentrate volatile and other incompatible elements, and thus might be the cause of mantle metasomatic events. They would be, in this model, the immediate sources of volcanic hotspots, although only a small fraction of all existing diapirs might reach the surface at a given time; many others might be disrupted by shearing before reaching the surface. Some of these features are shown in Fig. 4.

An important question is how the postulated heterogeneities could survive in a fully convective mantle, as the shearing in convective flow tends to smear out heterogeneities^{48,49}: the following arguments demonstrate the plausibility of heterogeneities surviving for thousands of millions of years. In a whole-mantle convection system, at present rates of seafloor spreading, it would take over 4,000 Myr for the mass of the mantle to pass within 100 km of the surface⁵⁰, and thus to undergo a significant melting and differentiation event; that is the mean residence time between major differentiation events is thousands of millions of years. For isolated more-viscous regions, shearing rates vary inversely as viscosity, so that refractory regions are likely to have low shearing rates. On the other hand, shearing rates of isolated less viscous regions are controlled by the viscosity of the surrounding mantle and thus will not be exceptionally large. In addition, the diapiric tendency of such regions, suggested above, will tend to enhance enriched heterogeneities.

A heterogeneous mantle is a natural outcome of the present tectonic regime, but the degree of chemical heterogeneity is difficult to estimate as it will be the result of a dynamic equilibrium

between the competing processes creating and destroying heterogeneities. This can be characterized in terms of the residence times of mantle material and survival times of heterogeneities. Residence times are clearly of the order of 10^9 years at present. Survival times depend on the rates of competing processes and these are difficult to estimate. The shearing rate can be characterized by the mantle overturn time which, at 30 mm yr^{-1} , is at least 300 Myr for the whole mantle. In a homogeneous fluid, heterogeneities can become very elongated by shearing in one overturn^{46,47}, but the mechanisms discussed above might easily extend the survival time well beyond one overturn time.

Because the Earth's heat flow was probably greater in the past, all processes would have been faster. Plate velocities are approximately proportional to the square of the heat flux⁵¹, but it is unlikely that the heat flux has been much more than twice its present value in the past 2,000 Myr (refs 33, 52). Thus residence times have probably been $> 1,000$ Myr for the past 2,000 Myr, and other rates would probably have changed in proportion.

O'Connell and Hager⁵⁰ have pointed out that residence times may be considerably less in the upper mantle than in the lower mantle because of the relatively rapid migration of ridges and trenches compared with convective velocities. Essentially, the more recently subducted material will have a greater chance of being returned to the surface by a passing ridge than deeper material. Thus this kinematic effect would tend to produce a stratification (but not necessarily layering) of the mantle in which the deeper material has been less differentiated than shallower material.

Conclusions

The Nd and Sr isotopic data clearly demand a mantle in which heterogeneities have existed for thousands of millions of years: the real question is the topology and distribution of the heterogeneities. In this sense the layered mantle model is a special case in which there are only vertical heterogeneities with sharp boundaries. Our heterogeneous mantle model is another type in which there is little or no mean vertical variation and in which the heterogeneities are isolated and have a range of chemical differences and a large range of sizes. The principal differences between these models lie in (1) the fraction of the mantle which has been strongly LIL-depleted, (2) the topology of the heterogeneities and (3) the existence of a reservoir of isotopically primitive material.

The principal question about the heterogeneous mantle model is probably the uncertainty of the survival time of the heterogeneities, while the principal question about the layered model may be the mechanism by which the layers are separated.

If some heterogeneities must exist within the layers of the layered mantle model, and if the heterogeneous model has some vertical stratification, then the distinctions between the models begin to blur. The real issue then is not a choice between two idealized models, but the accuracy with which the Earth's place in the spectrum of models can be determined. It is concluded here that no part of the spectrum of models discussed above can confidently be excluded at present.

I thank Don DePaolo, Gerry Wasserburg, Rodey Batiza, Larry Haskin and Keith O'Nions for constructive comments.

Structure of the neuraminidase gene in human influenza virus A/PR/8/34

Stan Fields & Greg Winter

MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

George G. Brownlee

Sir William Dunn School of Pathology, University of Oxford, South Parks Road, Oxford OX1 3RE, UK

The complete structure of the neuraminidase gene in influenza A/PR/8/34 has been determined by cloning into the bacteriophage M13 and sequencing with dideoxynucleotide chain terminators. The gene is 1,413 nucleotides long, codes for a protein of 454 amino acids and has five potential glycosylation sites. We suggest that the neuraminidase, unlike the influenza haemagglutinin, is oriented with its N-terminus buried in the viral membrane.

INFLUENZA A viruses have two surface antigens, haemagglutinin and neuraminidase, both of which can undergo extensive antigenic variation. The haemagglutinin binds the virus to sialic acid-containing receptors on the cell, but the role of the neuraminidase is still not fully understood (for reviews see refs 1, 2). The enzyme cleaves terminal *N*-acetylneuraminic acid (sialic acid) from carbohydrate chains in glycoproteins³, and its function may be to remove the carbohydrate residues from the virus envelope itself, thus eliminating receptors for the haemagglutinin and preventing self-aggregation of virion particles⁴. The removal of sialic acid also seems to facilitate proteolytic cleavage of the haemagglutinin, which is essential for infectivity^{5,6}, by exposing the site of cleavage on the haemagglutinin^{7,8}.

Although the haemagglutinin is the more significant factor in the immune response of the host organism, the neuraminidase is also involved in this response^{9,10}, as anti-neuraminidase antibodies can inhibit viral replication. Like the haemagglutinin, the neuraminidase can undergo either small changes in antigenicity^{11,12} (antigenic drift) or major changes (antigenic shift), in which the neuraminidases do not cross-react serologically¹¹. Antigenic shift in human influenza viruses occurred in 1957, when the N2 subtype replaced the N1. A comparison of the N-terminal amino acid sequences predicted from RNA sequencing¹³ showed that within a subtype there is a high degree of amino acid conservation, but between the different subtypes there is little homology after the first 12 amino acids.

Using recombinant DNA methods, we have sequenced the neuraminidase of the human strain A/PR/8/34 (H1N1, formerly designated H0N1) to provide a basic framework for both understanding the function of the protein and to further study the mechanism of antigenic drift and shift. From the sequence has emerged the possibility that in contrast to the haemagglutinin^{14–20}, the neuraminidase is bound to the viral membrane by its N-terminus.

Cloning and sequence analysis in M13

Three separate strategies were used to determine the sequence. As part of a 'shotgun' approach²¹ to sequence the eight single-stranded RNA segments in the influenza genome^{22–24}, restriction fragments derived from the whole genome were cloned into

the bacteriophage M13mp2 (ref. 25) or one of its derivatives^{26,27} and sequenced by the dideoxy technique²⁸. One *Hae*III clone contained the sequence of 444 nucleotides at the 3' end of the neuraminidase virion RNA (vRNA) as seen from a match with limited RNA sequence data for the related fowl plague virus (FPV) neuraminidase gene^{29,30}. Two other clones, derived from

Fig. 1 Summary of sequence evidence. Virion RNA was polyadenylated and double-stranded cDNA prepared using oligo(dT)_{12–18} priming and then loopback of the 3' end of the cDNA as described elsewhere²¹. Alternatively, the band 6 cDNA derived from 20 µg RNA was eluted from a 2.8% acrylamide/7 M urea gel³⁴ and annealed in 40 µl of 0.05 M NaCl, 0.01 M Tris-HCl pH 7.4, 0.01 M MgCl₂, 1 mM dithiothreitol (DTT) to 80 pmol of a 13-long synthetic oligodeoxynucleotides primer (see text) by boiling and then slowly cooling. Deoxynucleotide triphosphates to 0.5 mM and 2U DNA polymerase (Klenow fragment, Boehringer) were added and the reaction incubated for 1 h at 20 °C. Double-stranded molecules were cut by restriction enzymes; *Hae*III and *Alu*I fragments were blunt-end ligated to 10 ng *Hind*III-cut M13mp7 (ref. 27) in 10 µl of 0.05 M Tris-HCl pH 7.4, 0.01 M MgCl₂, 0.01 M DTT, 1mM rATP and 0.4U T4 DNA ligase. *Sau*96I fragments were first blunt-ended by incubation with the Klenow fragment of DNA polymerase³⁶ and then ligated as above. *Sau*3A fragments were ligated as described elsewhere²¹. DNA sequencing of M13 clones used a 30-base pair cloned primer⁶⁵ or 17-long oligodeoxynucleotide synthetic primer (from Dr M. J. Gait). RNA priming with restriction fragment primers was as described elsewhere²¹. Sequence reactions were electrophoresed on 6% acrylamide/7 M urea thin gels⁶⁶.

Fig. 2 Screening clones by dideoxythymidine tracks. *Hae*III clones were isolated as described in Fig. 1 legend. Screening using dideoxythymidine patterns as characterization³⁶ was on a 6% acrylamide/7 M urea thin gel⁶⁶ electrophoresed at 30 mA for 1.5 h. The 10 clones screened on this gel correspond to the following sequences (see Fig. 3): *a*, positions 1,347 to 1,413; *b*, 1,346–1,233; *c*, 1,346–1,233; *d*, 1,233–1,346; *e*, 727–878; *f*, 1,233–1,346; *g*, 710–726; *h*, 879–1,232; *i*, 710–726; and *j*, 1,347–1,413. Therefore clones *a* and *j* are identical, as are *g* and *i*. Clones *b* and *c* contain the same *Hae*III fragment but the opposite strand to clones *d* and *f*.

Table 1 Amino acid composition of the A/PR/8/34 neuraminidase

Amino acid	No.	Amino acid	No.
Ala (A)	16	Leu (L)	21
Arg (R)	20	Lys (K)	23
Asn (N)	25	Met (M)	7
Asp (D)	25	Phe (F)	16
Cys (C)	19	Pro (P)	21
Glu (E)	17	Ser (S)	51
Gln (Q)	11	Thr (T)	29
Gly (G)	44	Trp (W)	16
His (H)	10	Tyr (Y)	14
Ile (I)	41	Val (V)	28
Total no. amino acids 454			

*Hae*III and *Alu*I shotgun digests, contained an additional 500 nucleotides of neuraminidase sequence when overlapped by the other approaches.

To extend the 3' sequence, we prepared double-stranded cDNA (dsDNA) specific for segment 6, the neuraminidase gene^{31–33}, after first purifying the single-stranded cDNA (ssDNA) on an acrylamide gel³⁴. Clones derived from restriction digests of this dsDNA (Fig. 1) provided all of the remaining sequence of the neuraminidase gene, but not every overlap. The *in vitro* back-copy reaction was greatly facilitated by the use of a 13-long oligodeoxynucleotide primer³⁵ complementary to the 3' termini of the ssDNAs²⁹, which allowed synthesis of the complete sequence corresponding to the 5' end of the vRNA.

The final three overlaps were obtained from the third approach, in which restriction fragments derived from the replicative form of selected recombinant M13 clones were used as primers for dideoxy sequencing on a total vRNA template²¹.

Our approach was such that most sequences were determined more than once. As clones were obtained in either orientation in M13, 93% of the neuraminidase gene was determined on both strands, and of the remainder, most was sequenced from at least two independent clones. A total of 25 clones and three RNA primings was used in the complete sequence determination.

Because no clone is identified before its sequencing, particular restriction digests may yield an individual fragment in the same orientation in many clones. This problem of redundant information, inherent in a 'shotgun' strategy, was avoided by eliminating excess clones with a rapid characterization³⁶ that used only one of the four dideoxy tracks of a normal sequence reaction. Figure 2 shows the pattern of 'dideoxythymidine tracks' for one set of *Hae*III fragments derived from band 6 dsDNA. Such tracks show whether a clone has been obtained before and can indicate the length of an insert by inspection of the pattern for the M13 bands which follow the insert.

Nucleotide sequence of the neuraminidase gene

Figure 3 shows the complete sequence of the neuraminidase gene as the complementary RNA, corresponding to the messenger sense. The sequence is 1,413 nucleotides long, including 20 nucleotides 5' to the first AUG and 31 nucleotides 3' to the last codon. (The actual structure of the mRNA produced by the virus has the cap and several nucleotides donated by a host mRNA³⁷ and is an incomplete transcript of the vRNA³⁸.) Only one reading frame is open, beginning with the AUG at position 21 and terminating at a UAG at position 1,383; the next in-frame AUG is at position 450 and could code for a protein with a molecular weight (MW) of only 34,000 (see below). The other two reading frames are blocked by numerous termination codons. The predicted protein is co-linear with the RNA and occupies 97% of the coding capacity of the gene. Whereas band 8 (refs 39, 40) and possibly band 77 (ref. 21) of influenza virus code for two proteins, the neuraminidase gene is similar to the haemagglutinin gene^{16–20} in that it codes for a single protein. Previous sequencing of the A/PR/8/34 neuraminidase gene has determined limited sequences at the 3'

The influenza virus neuraminidase is an integral membrane protein and can only be released from the viral envelope by detergent or protease treatment⁵⁰. Previously it was suggested⁴⁵

Fig. 4 Comparison of membrane attachment sites. The N-terminal hydrophobic sequence of the neuraminidase is compared with the membrane attachment regions of isomaltase⁵⁹, glycophorin⁵⁴, vesicular stomatitis virus (VSV) glycoprotein⁵⁷, membrane-bound IgM⁵⁶ and the influenza virus haemagglutinin of A/PR/8/34 (unpublished data). The boxed region indicates the uncharged residues thought to span the membrane. The sequences have been aligned to show amino acid homology with the neuraminidase.

that a hydrophobic region was present at either the N- or C-terminus because the trypsin-released enzyme is smaller (by an estimated MW of 7,000 (ref. 45) or 12,000 (ref. 43)) than that derived from SDS disruption of the virion. This hydrophobic region would anchor the neuraminidase to the lipid bilayer of the virus. An examination of the A/PR/8/34 neuraminidase (Fig. 3) shows only one major hydrophobic region, located near the N-terminus and extending from amino acid residue 7 to 35. Of these 29 residues, 18 are hydrophobic, 11 are neutral and none is charged. The first trypsin-sensitive residues following this hydrophobic region are at positions 57(Lys) and 63 (Lys), and tryptic cleavage at either of these positions would result in a loss of MW of ~6,000, which is largely consistent with protein chemistry studies^{43,45}. A stretch of 16 uncharged amino acid residues (420–435) lies near the C-terminus, but of these only 5 are hydrophobic and seem unlikely to be sufficient for attachment of an integral membrane protein. Additional evidence favouring an N-terminal attachment comes from the finding that the small fragment lost on protease isolation of the enzyme from B/Lee⁴⁵ or FPV⁵¹ is rich in carbohydrate. In the A/PR/8/34 neuraminidase, potential carbohydrate attachment sites near the N-terminus occur at residues 44 and 58, and at least the first of these sites would be contained within the tryptic peptide presumed to be lost. No attachment sites lie within the C-terminal half of the molecule.

This membrane orientation would contrast with that of the influenza virus haemagglutinin⁵², and also of such membrane glycoproteins as erythrocyte glycophorin^{53,54}, HLA antigens⁵⁵, membrane-bound immunoglobulin μ chains⁵⁶ and vesicular stomatitis virus glycoprotein⁵⁷, all of which have C-terminal hydrophobic sequences. However, attachment of proteins to membranes through a hydrophobic N-terminus does have a precedent in the orientation of intestinal brush border aminopeptidase⁵⁸ and isomaltase^{58–60}. Figure 4 shows a comparison of the N-terminal hydrophobic sequence of the neuraminidase with other sequences involved in spanning the lipid bilayer; glycophorin shows the greatest sequence homology to the neuraminidase but all the sequences are similarly hydrophobic.

There is no experimental evidence to indicate whether the N-terminal hydrophobic sequence of the neuraminidase is a 'signal sequence' which is cleaved off⁶¹, or whether it remains

attached to the membrane, as has been suggested for the N-terminal region of isomaltase⁵⁹. However, in the two human subtypes, the total conservation of the first 12 amino acid residues¹³, of which the first six are hydrophilic, suggests that these have some critical role, which might be to interact with another protein or neuraminidase subunit. (Signal sequences of the haemagglutinins, which are cleaved off⁶², show hydrophobicity²⁰ but no conservation of amino acid sequence.) We suggest that the neuraminidase, like isomaltase, has an 'extended signal sequence'⁵⁹ which both transfers the protein across the membrane and remains in the bilayer to anchor the protein, with the first six residues protruding into the virion as a hydrophilic tail. The signal sequence may not be cleaved because the recognition sequence for the signal peptidase is lacking or unexposed⁵⁹. Such an N-terminal attachment favours a loop model⁶³ of protein translocation across a membrane, in which the signal sequence inserts into the lipid bilayer as a loop, with the first few amino acid residues remaining on the cytoplasmic side of the membrane. This hypothesis concerning N-terminal attachment of the neuraminidase could be tested directly by amino acid sequence analysis of the intact and trypsin-released enzyme.

Concluding remarks

The sequence of the neuraminidase gene allows us to suggest a possible role for a long hydrophobic sequence at the protein's N-terminus, but the regions involved in enzymatic activity and antigenicity remain undefined. Future sequences of other neuraminidase genes should reveal regions of homology within and between subtypes, and thus elucidate the phenomena of antigenic drift and shift at the molecular level. A more complete understanding of the neuraminidase, however, must await a three-dimensional structure of the molecule, which is at the preliminary stage for the N2 subtype⁶⁴.

We thank Mrs M. A. Robertson for supplying virus and RNA, R. Henderson, M. Bretscher and D. L. Bentley for discussions, A. D. McLachlan for the Chou–Fasman prediction and J. Messing for M13 vectors. A plasmid DNA primase active in discontinuous bacterial DNA replication

Brian M. Wilkins & Graham J. Boulnois

Department of Genetics, University of Leicester, Leicester LE1 7RH, UK

Erich Lanka

Max-Planck-Institut für Molekulare Genetik, Abteilung Schuster, Berlin-Dahlem, FRG

A DNA primase encoded by an IncIα plasmid promotes efficient DNA replication in a primase-defective mutant of Escherichia coli. This finding implies that the plasmid enzyme can prime discontinuous DNA synthesis of the bacterial chromosome. The plasmid gene encodes two large, antigenically related proteins which differ from E. coli primase.

A CENTRAL feature of DNA replication is the discontinuous synthesis of the strand that grows in the overall direction of 3' to 5'. DNA polymerases cannot initiate synthesis of the fragments involved in the process because these enzymes require the 3'-OH terminus of an oligonucleotide primer (for review see ref. 1). During replication of the *Escherichia coli* chromosome, the primer sequences are synthesized by the product of the *dnaG* gene², called primase³. This 60,000 molecular weight (*M_r*) single subunit protein⁴ is thought to act in a multi-enzyme complex that includes *dnaB* product⁵. Although certain virulent bacteriophages are known to encode DNA primases, these enzymes act in phage DNA replication in cooperation with specific phage DNA polymerases⁶⁻⁹.

Conjugative plasmids of the IncIα and IncIγ incompatibility groups¹⁰, represented by Coll, R64, R144 and R621a, can suppress temperature-sensitive *dnaG* mutations, allowing DNA replication and colony formation at high temperature^{11,12}. The relevant gene is designated¹³ *sog*, conferring a phenotype of Sog⁺. Suppression of *dnaG* lesions requires derepression of the plasmid transfer genes by a *drd* mutation, implying that the physiological role of *sog* product may be in conjugation. Recently, a novel DNA primase has been purified from bacteria containing the IncIα plasmid R64*drd*-11 and characterized¹⁴. The enzyme has a low template specificity *in vitro*; it can substitute for the activities of *dnaB*-*dnaC*-*dnaG* products, *E. coli* RNA polymerase and *dnaG* product in priming synthesis of DNA complementary to viral strands of phages ΦX174, fd and G4, respectively.

The studies reported here show that the IncIα plasmid product responsible for suppressing bacterial *dnaG* mutations is a DNA primase. This finding implies that the plasmid enzyme can substitute for *E. coli* primase to promote efficient discontinuous synthesis of the bacterial chromosome and indicates that primer-generating enzymes other than *dnaG* protein can act in bacterial DNA replication. The approach has involved the

cloning of the *sog* gene of Coll*drd*-1 and analysis of proteins encoded by the parental and recombinant plasmids. The *sog* gene is shown to encode two antigenically related proteins. Primase activity is localized in part of the larger molecule.

Table 1 Plasmids that suppress *dnaG3* specify the IncIα plasmid primase

Strain	Colony formation 40 °C/30 °C	DNA synthesis at 41 °C (10 ⁻³ c.p.m. per ml per A ₄₅₀ unit)	Primase activity (mU per mg CCE)
BW86	<10 ⁻⁷	11	ND
BW86 (pBR325)	<10 ⁻⁷	16	ND
BW86 (Coll)	2.7 × 10 ⁻⁷	22	1
BW86 (Coll <i>drd</i> -1)	2.1 × 10 ⁻¹	342	213
BW86 (pLG215)	1.8 × 10 ⁻⁴	262	182
BW86 (pLG214)	1.0	341	221

Colony formation gives the fractional yield of colonies at the indicated temperatures. Overnight cultures in nutrient broth were diluted suitably and plated on prewarmed nutrient agar. Thymine (20 μg ml⁻¹) was added to all media. DNA synthesis indicates ³H-thymine incorporated in 60 min at 41 °C. Bacteria, growing exponentially in SGC medium containing deoxyguanosine and thymine (3 μg ml⁻¹)¹¹, were incubated at 41 °C for 5 min before addition of ³H-thymine to 7.5 μCi ml⁻¹ (320 mCi mmol⁻¹). A₄₅₀ of cultures was measured at zero time. Primase was assayed using bacteria growing exponentially in broth. 2 × 10⁹ bacteria were gently lysed using the non-ionic detergent Brij 58 in conjunction with lysozyme²⁶. Following centrifugation (80,000 g, 30 min), primase activity and protein concentration were measured as described previously¹⁴. All liquid media for strains harbouring pBR325, pLG214 or pLG215 contained tetracycline (10 μg ml⁻¹) and agar contained ampicillin (25 μg ml⁻¹). 1 unit of primase incorporated 1 μmol of dTMP in the conditions used. CCE, crude cell extract; ND, not detectable.

Cloning of the *sog* gene

The small multicopy plasmid pBR325 was used as the vector for cloning. This plasmid¹⁵ carries genes conferring resistance to ampicillin (Ap^r), tetracycline (Tc^r) and chloramphenicol (Cm^r) and contains a single endonuclease *EcoRI* cleavage site in the latter. Fragments of *ColIdrd-1*, generated by *EcoRI* restriction endonuclease, were ligated into this site in pBR325 and the DNA was used to transform a temperature-sensitive *dnaG3* mutant (BW86, *dnaG3 leu thyA deoB rpsL ΔchlA-uvrB ColI^r*; ref. 13). Transformants harbouring *Sog*⁺ plasmids could be isolated using the following strategy. Ap^r transformants were first selected at 30 °C and allowed to grow into small colonies, when they were replica plated. About 1% of the replicas grew at 40 °C to give distinct colonies; these were found to contain *Sog*⁺ recombinant plasmids.

The plasmid (pLG211) in one of these strains was characterized. Cleavage with *EcoRI* restriction endonuclease generated three DNA fragments with estimated sizes of 5.9 kilobases (which corresponds to the vector), 7.9 and 0.27 kilobases. The smallest of these DNA fragments was next removed by cleaving pLG211 with *EcoRI* endonuclease followed by ligation to give pLG215. The latter plasmid specifies resistance to ampicillin

Fig. 1 Map of pLG215 showing the position of the 1.5-kilobase deletion mutation present in pLG214. The vector, pBR325, is drawn in double lines (0 to 5.9 kilobases). The positions of the Tc^r and Ap^r genes are derived from maps of pBR322 and pBR325 (refs 15, 27). Mapping was carried out by subjecting restriction endonuclease-cleaved DNA to electrophoresis in 0.5% or 2% agarose gels using procedures similar to those described elsewhere^{28,29}, except that double digestions were carried out in 6.6 mM $MgCl_2$, 60 mM NaCl, 6.6 mM 2-mercaptoethanol and 6.6 mM Tris-HCl (pH 7.4). Molecular weight markers included phage λ DNA cleaved with *EcoRI* and *HindIII* endonucleases in single or double digests³⁰ and *Taq*YI-cleaved pBR322 (ref. 31). Lengths (kilobases) of DNA fragments in *Bgl*II+*EcoRI* double digests were 5.9, 4.4, 3.3 and 0.23. Lengths of DNA fragments generated by *Bgl*II+*HindIII* endonucleases were 4.9, 4.6 and 4.4 kilobases. The 4.4-kilobase DNA fragment was replaced by a 2.9-kilobase fragment in corresponding digests of pLG214. The *Bam*HI and *Sal*I cleavage sites were mapped using sizes of fragments generated in appropriate double digests with *HindIII* or *EcoRI* endonucleases. Construction of pLG215 is summarized in the text. pBR325 was isolated by a cleared lysate method³². *ColIdrd-1* was purified using a Sarkosyl lysis method³³ with the modification that DNA in supernatant was concentrated by ethanol precipitation following extraction with phenol. Ligations were done at 4 °C in 60 mM Tris-HCl (pH 7.4), 10 mM $MgCl_2$, 10 mM dithiothreitol, 0.1 mM ATP, 0.005% gelatin and T4 DNA ligase (from Dr Ron Wilson).

Fig. 2 Electron micrograph of a pLG214/pLG215 heteroduplex DNA molecule showing a deletion loop, indicated by the arrow. The plasmids were cleaved at the unique *HindIII* site (Fig. 1) before formation of heteroduplexes. The mean fractional length of the short arm of 12 molecules was 0.48. The inset shows a heteroduplex DNA molecule prepared following digestion of pLG214 and pLG215 with *EcoRI* endonuclease. This digestion separates the cloned fragment of *ColIdrd-1* from the vector (Fig. 1). The mean fractional length of the short arm of 18 molecules was 0.22 (s.d. $\pm$ 3.7%) of the duplex DNA. The estimated length of the duplex DNA is 6.4 kilobases, which is the size of the relevant *EcoRI* fragment in pLG214. Molecules were prepared and examined using methods described elsewhere³⁴.

and to tetracycline but not to chloramphenicol, indicating insertion-inactivation of the Cm^r gene of pBR325. Plasmid pLG215 retains the 7.9-kilobase *EcoRI* restriction fragment of *ColIdrd-1* which was found to contain two endonuclease *Bgl*II cleavage sites (Fig. 1). Table 1 shows that the plasmid suppresses the *dnaG* mutation in BW86 as measured by extensive DNA synthesis at 41 °C and colony formation at 40 °C. However, by both criteria, pLG215 suppressed the *dnaG* lesion less efficiently than *ColIdrd-1*.

BW86(pLG215) is deficient in accumulating DNA at high temperature. This was established by monitoring absorbance and trichloroacetic acid (TCA)-precipitable ³H-thymine in a uniformly labelled culture: following transfer of an exponentially growing culture from 31 °C to 41 °C, A_{450} increased by a factor of 7.0 in 120 min at high temperature whereas DNA increased by a factor of 3.6. No such disparity was detected at 31 °C. This finding, together with the heterogeneous size of colonies formed at 40 °C, suggested that an undefined mutation might be necessary to allow BW86 (pLG215) to form colonies at high temperature. Chromosomal mutation is inferred from studies with six independently isolated colonies formed at 40 °C. The plasmids in these strains appeared identical to pLG215 as judged by analysis of *EcoRI* restriction digests and, following reintroduction of the plasmids into BW86, by the ability of the resulting transformants to form colonies at 40 °C. Plasmid-free segregants of the six original strains were temperature sensitive but they acquired a fully thermoresistant phenotype with high frequency in a second round of transformation with pLG215.

Fig. 3 Analysis by SDS-gel electrophoresis of proteins encoded by *Sog*⁺ plasmids. Lanes *a*–*c* show a fluorograph of ³⁵S-labelled proteins synthesized in minicells containing: *a*, pBR325; *b*, pLG215; *c*, pLG214. Lanes *e*–*h* show Coomassie blue-stained proteins in extracts of: *e*, BW86 (pLG215); *f*, BW84 (pLG216); *g*, BW86 (pLG214); *h*, BW86 (pBR325). Molecular weight standards (lane *d*) are myosin (*M_r* 212,000), *E. coli* RNA polymerase β'-subunit (*M_r* 165,000), β-subunit (*M_r* 155,000), σ-subunit (*M_r* 90,000) and α-subunit (*M_r* 39,000). Minicells were purified³⁵ from plasmid-containing derivatives of DS410 (ref. 36). Proteins were labelled for 90 min at 37 °C in M9 minimal medium containing ³⁵S-methionine (100 μCi ml⁻¹, 1 Ci mmol⁻¹) and Difco methionine assay medium (1.6 mg ml⁻¹). After a 10-min chase with methionine-supplemented broth, minicells were lysed by boiling in cracking buffer (62.5 mM Tris-HCl (pH 6.8), 3% SDS, 10% glycerol, 5% β-mercaptoethanol). About 150,000 c.p.m. were added per slot. Conditions for gel electrophoresis³⁷ and fluorography³⁸ have been described. Cell extracts were prepared from 1 ml of stationary phase bacteria at *A*₄₅₀ of 1. Cells were lysed in 30 μl cracking buffer and the total lysate was added to the slot.

Thus, the strains contain a chromosomal mutation which does not revert the *dnaG3* lesion but allows efficient colony formation at 40 °C in the presence of the *Sog*⁺ plasmid.

The recloning experiment which generated pLG215 from pLG211 gave rise to a BW86 transformant strain that was atypical in forming colonies at 40 °C with a frequency of 1. This phenotype was determined by a plasmid designated pLG214 (Table 1). Endonuclease *Eco*RI cleaved pLG214 to produce DNA fragments of 5.9 and 6.4 kilobases, suggesting deletion of 1.5 kilobases from the segment of *Colldrd-1* present in pLG211 and pLG215. Endonuclease *Bgl*II digests showed that the deletion affects the 4.4-kilobase *Bgl*II fragment found in pLG215 (Fig. 1). This location was confirmed by analysis of

pLG214/pLG215 heteroduplex DNA molecules which demonstrated a deletion loop almost equidistant from the termini generated by cleavage of the plasmids at the unique *Hind*III site (Fig. 2). Heteroduplex DNA formed between endonuclease *Eco*RI-cleaved pLG214 and pLG215 indicated a single internal deletion mapping about 1.4 kilobases from the nearer junction of the cloned DNA and vector (Fig. 2 inset).

Sog⁺ recombinant plasmids specify DNA primase

Table 1 shows that bacteria harbouring *Sog*⁺ recombinant plasmids produce DNA primase. The assay measured the ability

Fig. 4 Glycerol gradient centrifugation of DNA primase specified by pLG214. 47 μg of protein in 0.2 ml of gradient buffer was layered on a 3.7 ml, 18–43% (wt/vol) glycerol gradient in 20 mM Tris-HCl (pH 7.6), 200 mM NaCl, 1 mM dithiothreitol and 1 mM EDTA. Centrifugation was for 24 h in the Beckman SW-60 rotor at 60,000 r.p.m. Sedimentation was from right to left. 173-μl fractions were assayed for primase activity (shaded histogram). Aliquots (150 μl) were subjected to SDS-gel electrophoresis (lower panel). The lane at the right contained 1.9 μg of primase preparation. Yeast alcohol dehydrogenase (ADH, *M_r* 141,000), *E. coli* alkaline phosphatase (AP, *M_r* 80,000), ovalbumin (OVA, *M_r* 43,000) and lysozyme (LYS, *M_r* 13,970) were run in parallel as markers. Primase was purified from BW86 (pLG214). 280 g of wet cell paste in 50 mM Tris-HCl (pH 7.6), 100 mM NaCl and 5% sucrose was frozen and thawed and then supplemented with EDTA (1 mM), spermidine-3HCl (5 mM), Brij 58 (0.25%) and lysozyme (0.04%) at a final concentration of 1 g cells per 2.5 ml. After 90 min at 0 °C the suspension was centrifuged (90 min, 70,000 g). All subsequent buffers were supplemented with 10% glycerol, 1 mM EDTA and 1 mM dithiothreitol. Supernatant containing 8.3 g of protein was added to a heparin-Sepharose CL6B column and eluted by applying a 600 ml gradient of 0.05–1 M NaCl in 20 mM Tris-HCl (pH 7.6). Primase activity eluted at 0.5 M NaCl. Active fractions (containing 86 mg of protein) were applied to a hydroxyapatite column and protein was eluted by a 300-ml gradient of potassium phosphate pH 7.0 (20–400 mM). Enzyme activity eluted at 150 mM phosphate. Active fractions (42.5 mg of protein) were applied to a phosphocellulose column (Whatman P11) and a 300-ml 0–0.8 M NaCl gradient was applied which eluted primase at 300 mM. After dialysis against buffer A (20 mM Tris-HCl pH 7.6, 50 mM NaCl), 30 ml (8.1 mg of protein) was applied to a DEAE-Sephacel column. Primase activity failed to bind and was washed off with buffer. This fraction (3.9 mg of protein) was applied to a second phosphocellulose column. Active fractions were concentrated by dialysis against 20% polyethylene glycol in buffer A. Yield was 2.6 mg of protein and 80% of activity. The enzyme remains stable at –20 °C for at least 6 months.

of crude cell extracts to stimulate conversion of single-stranded DNA of phage fd to duplex replicative form in a receptor extract containing rifampicin¹⁴. The antibiotic was added to inhibit RNA polymerase, the enzyme naturally required for priming DNA synthesis on viral strands of phage fd¹⁶. A 200-fold higher activity was detected in ColI-containing strains when the plasmid carried the *drd* mutation. This correlates with the requirement for a *drd* mutation in plasmid-mediated suppression of the *dnaG* lesion. *Sog*⁺ recombinant plasmids pLG214 and pLG215 directed synthesis of similar high activities of the primase, indicating that the gene specifying the enzyme is in the same *EcoRI* fragment of ColI*drd-1* as the gene that causes suppression of *dnaG* mutations.

Polypeptides encoded by *Sog*⁺ plasmids

Plasmids pLG214 and pLG215 segregate into chromosomeless minicells, providing a system for identification of polypeptides encoded by the cloned fragment of ColI*drd-1* that contains the *sog* gene. Comparison of ³⁵S-methionine-labelled proteins synthesized in pBR325- and pLG215-containing minicells (Fig. 3, lanes a, b) shows that the 7.9-kilobase *EcoRI* restriction fragment of ColI*drd-1* encodes two polypeptides of *M*_r 240,000 and 180,000. Assuming these to be encoded totally by the ColI component of the recombinant plasmid, coding sequences comprising about 0.82 and 0.62 of the DNA, respectively, will be required. The sum of these values implies that the genetic determinants of the two polypeptides share common nucleotides. Lane c indicates that the 6.4-kilobase deletant fragment of ColI*drd-1* in pLG214 encodes two smaller polypeptides of *M*_r 87,000 and 42,000.

The 240,000 *M*_r protein was also detected in extracts of cells carrying pLG215 or ColI*drd-1* but not pLG214, pBR325 or ColI. Representative results are in Fig. 3, lanes e, g and h. The protein is the largest of the species that stain with Coomassie blue. Lane f contains an extract of BW84 (pLG216). BW84 is the *uvrB*⁺-*chlA*⁺ parent¹³ of BW86 and pLG216 is a *Sog*⁺ plasmid identified after *in vitro* mutagenesis of pLG211 with hydroxylamine¹⁷. The strain was fortuitously isolated during the screening of extracts of appropriate Ap^r BW84 transformants for primase activity. It has the advantage of producing about five times more plasmid primase activity than bacteria harbouring ColI*drd-1* or pLG215; it also overproduces the 240,000 *M*_r protein.

Purification of a DNA primase and antigenic relationship of polypeptides

A plasmid DNA primase was purified from BW86 (pLG214) using the procedure given in Fig. 4 legend. Chromatography on heparin-Sepharose was very useful because it allowed a 100-fold purification of enzyme in the first step starting with a crude cell extract. The preparation of DNA primase contained one major protein of *M*_r 87,000 which co-sedimented with enzyme activity through a glycerol gradient (Fig. 4). Its sedimentation coefficient was calculated to be 4.2S, indicating that it functions as a single subunit protein. This DNA primase is assumed to be the larger of the two polypeptides detected in pLG214-containing minicells (Fig. 3, lane c).

Using antiserum raised against this DNA primase preparation, immunological studies indicated an antigenic relationship between the two polypeptides encoded by the fragment of ColI*drd-1* present in pLG215 and the smaller pair of proteins specified by pLG214. The procedure, adapted from that of Towbin *et al.*¹⁸, involved separation of proteins in crude cell extracts by SDS-gel electrophoresis followed by their electrophoretic transfer to a nitrocellulose sheet. The resulting blot was incubated first with antiserum raised¹⁹ in a rabbit against the pLG214-specified primase and then with fluorescein-conjugated goat anti-rabbit immunoglobulins to detect bound antibody.

Figure 5, lanes c and d, show that antiserum reacted with two polypeptides of *M*_r 240,000 and 180,000 in extracts of bacteria harbouring pLG216 or pLG215. In the case of BW84

Fig. 5 Immunological analysis of proteins encoded by *Sog*⁺ plasmids. Crude cell extracts were prepared and separated on an SDS-polyacrylamide gel, as described in Fig. 3 legend. Proteins were transferred electrophoretically to a nitrocellulose membrane and reacted with antiserum as described elsewhere¹⁸. Antiserum against purified pLG214-specified DNA primase was applied in a 1:150 dilution. Fluorescein-conjugated goat anti-rabbit IgG were diluted 1:50. Lane a, BW86 (pBR325); b, BW86 (ColI*drd-1*); c, BW84 (pLG216); d, BW86 (pLG215); e, BW86 (pLG214); f, DNA primase purified from BW86 (pLG214). Migration of molecular weight standards, given under Fig. 3, is shown on the right margin.

(pLG216), the strain that overproduces plasmid primase, a third immunogen (*M*_r 168,000) was also apparent (lane c). The significance of this protein has not been established. Lane e shows that BW86 (pLG214) contains two smaller immunogens (*M*_r 87,000 and 42,000). Only the larger, assumed to be the DNA primase, was present in the antigen (lane f). Preimmune serum was unreactive. Two observations suggest that these polypeptides are encoded solely by the cloned fragment of ColI*drd-1* and are not products of fused cloned and vector DNA. First, antiserum did not react with protein in an extract of cells harbouring pBR325 (lane a). Second, the 240,000 and 180,000 *M*_r polypeptides are indistinguishable by size from a pair of polypeptides detected in bacteria containing the parental plasmid, ColI*drd-1* (lane b).

Antiserum, but not preimmune serum, inhibited the ability of crude extracts of BW86 containing either ColI*drd-1* or pLG215 to promote DNA synthesis on viral strands of phage fd (data not shown). Thus, the primase encoded by these plasmids is structurally related to the 87,000 *M*_r primase of pLG214, the antigen. Similarly, antiserum blocked activity of the primase specified by two other IncIα plasmids, R144*drd-3* and R64*drd-11*, and the IncIγ plasmid, R621a. In contrast, the antibodies failed to inhibit DNA synthesis on viral strands of phages ΦX174 and G4 in an ammonium sulphate fraction¹⁴ of *dna*⁺ cells (data not shown). Thus, the DNA primases encoded by IncIα plasmids are antigenically unrelated to the *E. coli* enzyme.

Products of the *sog* gene

The following hypothesis is proposed to explain the protein relationships. The *sog* gene encodes a pair of sequence-related

polypeptides of apparent molecular weight 240,000 and 180,000. The deletion mutation in pLG214 disrupts synthesis of the C-terminal segments giving a pair of truncated polypeptides (M_r 87,000 and 42,000). The smaller protein in each pair may be a processed product of the larger or may be generated from a second translational start within the *sog* gene without a change in reading frame. The latter possibility, for which gene A of Φ X174 is a precedent²⁰, is favoured by the properties of two *Sog*⁻, primase-defective, amber mutants of pLG211; these specify synthesis of the 180,000 M_r protein but not the 240,000 M_r protein (to be published). It is proposed that DNA primase activity requires part of the N-terminal sequence of the 240,000 and 87,000 M_r proteins. This is consistent with the properties of the amber mutants and the finding that the 87,000 M_r protein, but not the 42,000 M_r protein, purified as a DNA primase. Furthermore, primase activity *in vitro* has been detected in a partially purified preparation of the 240,000 M_r polypeptide (in preparation).

Suppression and DNA primase

The deletion in pLG214 enhances the efficiency of suppression of the *dnaG3* mutation and generates a truncated protein that purifies as a DNA primase. We therefore conclude that plasmid primase is the enzyme responsible for suppression. The enzyme is distinguishable from *dnaG* protein on the basis of molecular weight, antigenic determinants and product of reaction; *in vitro* it directs synthesis of a primer that contains cytidine or cytidine 5'-monophosphate at the 5' terminus (E.L., in preparation) and not an adenosine nucleotide as in the primer synthesized by *dnaG* protein. Thus, the phenomenon of suppression reflects the substitution of an unrelated plasmid enzyme for *E. coli* primase in the discontinuous synthesis of bacterial DNA and any primase-dependent event that may occur at the origin of DNA

replication. The plasmid primase can also substitute *in vivo* during replication of phage λ DNA (unpublished data) and of ColEI-type replicons like the recombinant plasmids used here. Thus DNA primases encoded by Inc α plasmids are remarkable for their ability to use a large variety of templates¹⁴. IncP plasmids, represented by RP4, also specify a DNA primase active in the assay reported here (E.L., unpublished data). This enzyme may also have the potential to act in bacterial DNA replication because derivatives of another IncP plasmid, R68-45, can suppress the *dnaG3* mutation²¹.

Inc α plasmid primase seems to cooperate with DNA polymerase III holoenzyme. Extension of primers *in vitro* requires DNA polymerase III and the *dnaZ* protein¹⁴, which is a component of the holoenzyme²². *In vivo*, bacterial DNA replication in the *dnaZ* mutant, AX727, remains temperature sensitive in the presence of ColIdrd-1 (unpublished data).

ColIdrd-1 and R64drd-11 also fail to suppress the temperature sensitivity of DNA replication in *dnaB70* and *dnaB43* mutants^{23,24}, implying that plasmid primase cannot bypass the requirement for *dnaB* protein. The *dnaB* product is thought to act in discontinuous DNA synthesis as a 'mobile promoter' for primer synthesis by bacterial primase⁵. Unlike the latter enzyme, R64drd-11 primase acts independently of *dnaB* protein in the priming reaction on single-stranded DNA of phage Φ X174¹⁴. Thus, the requirement for *dnaB* protein in plasmid primase-mediated DNA replication may reflect involvement of the protein in some process other than the priming reaction—possibly, unwinding of the DNA helix²⁵.

We thank Georg Stöffler for preparing antiserum, Brigitte Geschke and Marianne Schlicht for assistance, Pam Kramer for the electron microscopy, and Alec Jeffreys for his interest. Part of this work was supported by an EMBO short-term fellowship to B.M.W. and SRC grant GR/B24172. We thank H. Schuster for encouraging the collaboration.

The *E. coli* β -lactamase attenuator mediates growth rate-dependent regulation

Bengtåke Jaurin, Thomas Grundström, Thomas Edlund & Staffan Normark

Department of Microbiology, University of Umeå, S-901 87 Umeå, Sweden

We have identified a new control or attenuator region in the chromosomal β -lactamase operon of Escherichia coli. A single base alteration within this attenuator led to a loss in the cell's ability to coordinate its content of β -lactamase with growth rate. We suggest a mechanism through which this mode of regulation operates.

MOST of the more abundant *E. coli* proteins increase in specific amounts with increasing growth rates¹. This group of proteins includes ribosomal proteins, elongation factors, aminoacyl

tRNA synthetases and subunits of RNA polymerase. Also, the amount of rRNA and tRNA increases coordinately with growth rate. Both active and passive regulatory models have been

Fig. 1 Relative amount of β -lactamase at different growth rates at 37 °C in *E. coli* K12 strains LA51 (*ampP15G16*) and TE18 (*ampP15G16*, *ampL35A*). The relative amount of β -lactamase per total protein was determined with rocket immunoelectrophoresis as previously described³ and plotted as a function of the first-order constant for growth (k), as calculated from the expression $k = \ln 2/\text{mass doubling time in hours}$. The media used were as follows: medium E + glycerol, medium E + glucose, medium E + glucose + casamino acids, and LB medium³.

proposed to explain the positive correlation between the production of these components of the translation machinery and growth rate².

The relative amount of chromosomally encoded β -lactamase of *E. coli* K12 also increases with growth rate³. This periplasmic enzyme hydrolyses the β -lactam ring of both cephalosporins and penicillins including ampicillin. Its structural gene, *ampC*, has been located at 93.8 min on the *E. coli* linkage map^{4,5}. The strict linear relationship between β -lactamase production and ampicillin resistance enables one to isolate mutants with altered production of β -lactamase by selecting on plates containing different concentrations of ampicillin^{4,6}.

Ampicillin-resistant mutants have been found to carry either *cis*-dominant mutations in a control sequence region denoted *ampA* that is adjacent to *ampC*⁶, or multiple tandem repeats of DNA segments encoding the structural gene⁷. The regulatory region *ampA*, as well as the structural gene *ampC*, have been cloned on a ColE1 hybrid plasmid and by further subcloning localized to a 1,370-base pair DNA segment⁶.

We describe here the sequence and structure of the control region for the β -lactamase gene, *ampC*, in wild-type *E. coli* and two regulatory mutants, and suggest a mechanism whereby the control region regulates transcription in response to the quantity of ribosomes per cell.

A mutation in the control region abolishes the positive correlation between β -lactamase production and growth rate

Strain LA5 is wild type for β -lactamase production. The concentration of ampicillin on broth plates required to kill 50% of the applied wild-type cells (LD_{50}) is $1 \mu\text{g ml}^{-1}$. Strain LA51 is an ampicillin-resistant transductant of strain LA5 (ref. 4). It shows an LD_{50} value of $15 \mu\text{g ml}^{-1}$ of ampicillin, and a corresponding 15-fold increase in β -lactamase production. This strain carries a *cis*-dominant regulatory mutation denoted *ampA1* (ref. 4), which we have recently localized within a

370-base pair DNA segment adjacent to *ampC*⁶. From strain LA51, spontaneous mutants with a further increase in ampicillin resistance have been isolated⁶, one of which, TE18, exhibiting an ampicillin resistance of $62 \mu\text{g ml}^{-1}$ (LD_{50}), carries a second mutation in the same 370-base pair regulatory region for *ampC*.

We have previously demonstrated that the specific amounts of β -lactamase produced both in the wild-type strain LA5 and in the mutant strain LA51 increase proportionally with growth rate³. In contrast, when the growth rate responses of the mutant strains LA51 and TE18 were compared (Fig. 1) it was evident that the growth rate-dependent regulation of β -lactamase had been abolished in the double mutant TE18. Thus, the level of β -lactamase in strain TE18 was much higher than that of LA51,

Fig. 2 A, restriction map of the *amp* region and sequencing strategy. The dashed line designates the insertion point of the transposable element $\gamma\delta$ (ref. 6). The box indicates the position of the structural gene, *ampC*. The direction of sequencing from the 5' and 3' ends of DNA cut with *AvaI* (*SmaI*) is indicated by arrows. The 1.5-kilobase *XhoI*-*SacII* fragments from plasmids pNU6, pNU28 and pNU35 were prepared from polyacrylamide gels²¹ and cleaved with *AvaI*. For the 5'-end labelling, 5–30 pmol of 5' ends were incubated in 10 μl of 50 mM Tris-HCl, pH 8.0, with 0.03 units of bacterial alkaline phosphatase at 45 °C for 30 min. 1 μl of 50 mM EGTA was added and the solution was heated at 65 °C for 15 min. 150 μCi vacuum-dried [γ -³²P]ATP ($>5,000 \text{ Ci mmol}^{-1}$, Radiochemicals) was dissolved in 9 μl of H_2O and transferred to the DNA mixture. 2.5 μl of 0.5 M Tris-HCl, pH 7.6, 0.1 M MgCl_2 , 50 mM dithiothreitol (DTT), 1 mM spermidine, 1 mM EDTA were added and the reaction mixture incubated with 5 units of T4 polynucleotide kinase (Biolabs) at 37 °C for 25 min. After one phenol extraction, labelled DNA was isolated by gel filtration on a Sephadex G-100 column. The 3'-end labelling was in principle as described by Schwartz *et al.*²². However, [α -³²P]dCTP (Radiochemicals) was used, followed by a chase for 10 min at 25 °C with 0.05 mM of cold dCTP. The labelled fragments were cleaved with *Bst*NI (cleaves 625 base pairs to the right of the *SacII* cut). The *AvaI*-*Bst*NI fragments were purified from polyacrylamide gels²³ and subjected to the nucleotide sequencing procedure described by Maxam and Gilbert²³. The degradation products were separated on 0.5-mm thick 8% and 20% sequencing gels with subsequent autoradiography at -20°C . B, nucleotide sequence of the control region and the N-terminal part of *ampC*. Start of transcription is marked by +1 and the wavy arrow. The major and minor termination points of the short transcript are indicated by vertical solid and dashed arrows, respectively. The stem and loop structure is marked by horizontal arrows and stippled boxes. Solid lines designate possible base pairing with the 3' end of 16S RNA¹⁸. Met and Och designate initiation codon (methionine) and stop codon (ochre), respectively. The limit between the presumed signal peptide and the mature β -lactamase is marked by the vertical dashed line. The positions of the G-C insertion in *ampP15G16* and the A-T transversion in *ampL35A* are represented by vertical arrows. The -35 and -10 promoter regions are marked by stippled boxes.

and it did not change when the steady-state growth rate was varied by a factor of three.

Establishment of the DNA sequences in the wild-type and regulatory mutants

Plasmid pNU6 is a pBR322 derivative which carries the *ampC* gene and the wild-type regulatory region. Plasmids pNU28 and pNU35 carry *ampC* and the mutated control regions of strains LA51 and TE18, respectively⁶. Figure 2A shows a restriction map of a 2.5-kilobase DNA segment containing the β -lactamase gene. We have previously located the regulatory mutations of LA51 and TE18 between the *XhoI* site and the insertion point for the transposable element $\gamma\delta$ (ref. 6) as shown in Fig. 2A. The nucleotide sequences from the *AvaI* (*SmaI*) site towards the *SacII* site were obtained by both 5'- and 3'-end-labelling and are presented in Fig. 2B. This stretch of DNA was sequenced from plasmids pNU6, pNU28 and pNU35. To localize the beginning of the coding region for *ampC*, the order of the 12 N-terminal amino acids of purified chromosomal β -lactamase was determined by Edman degradation (manuscript in preparation). There was perfect correspondence with the codons from base pairs +117 to +152. The nearest predicted translation start sequence appeared 19 codons before that for the N-terminal amino acid (alanine) of the purified enzyme. These data are consistent with the interpretation that the translational product of *ampC* carries a 19-amino acid N-terminal extension. This stretch of amino acids has all the common structural features of a signal peptide⁸.

Upstream of the transcriptional start base (+1, see below), sequences at nucleotide positions -13 to -8 (-TACAAT-) and -35 to -30 (-TTGTCA-) both show extensive homologies with the conserved -10 and -35 regions of prokaryotic promoters⁹. Also, the sequences between and surrounding these regions show homology with known promoter sequences. When the DNA sequence of the same segment as in pNU6 was determined with the mutant plasmid pNU28, the only difference from the wild type was an insertion of a G·C base pair between positions -16 and -15 (Fig. 2B). Thus, this mutation, denoted *ampP15G16* (previously *ampA1*), which causes a 15-fold increase in β -lactamase synthesis, was located in the presumed *amp* promoter between the conserved -35 and -10 regions.

In the wild-type plasmid pNU6 and in plasmid pNU28, we find a 9-base pair long, exclusively G↔C-containing, dyad symmetry sequence at nucleotide positions +17 to +25 and +29 to +37. This symmetrical DNA sequence is followed by a stretch of four T residues on the noncoding strand. Many terminators for the *E. coli* RNA polymerase have similar sequence features¹⁰. Plasmid pNU35, carrying the *ampC* region of strain TE18, contained in addition to the mutation *ampP15G16*, a C·G to A·T transversion at position +35 (Fig. 2B). This *amp* leader mutation, denoted *ampL35A*, has occurred within the postulated terminator sequence.

In vitro transcription from DNA segments carrying a wild-type or a mutated regulatory region

The 1.5-kilobase *SacII*-*XhoI* DNA fragment which carries the entire sequenced region shown in Fig. 2B, was isolated from plasmids pNU6, pNU28 and pNU35 and added individually to an *in vitro* transcription system. The results are shown in Fig. 3A. From the pNU6 fragment that carries the wild-type regulatory sequence, both a long and a short [α -³²P]CTP-labelled transcript were obtained (L and S in Fig. 3A). The distance from the initiation site for transcription (see below) to the *XhoI* end of the *SacII*-*XhoI* fragment is ~340 base pairs. The long transcript is approximately this length and therefore probably represents a run-off transcript. Furthermore, when the DNA fragment was cleaved at the *AvaI* (*SmaI*) site located 161 base pairs from the *XhoI* site, the 340-base pair long transcript was not found.

Instead, as expected, a new transcript (~180 bases long) appeared (data not shown). The short transcript (S in Fig. 3A) was shown by RNA sequencing analysis to be 41 bases long (see below). The DNA sequence (Fig. 2B and data not shown)

Fig. 3 In vitro transcription and RNA sequencing of the *amp* leader region.

A shows transcripts obtained from the 1.5-kilobase *XhoI*-*SacII* fragments (see Fig. 2A) carrying different *amp* alleles. The *in vitro* transcription reactions contained 0.25 μ g of the DNA fragment, 2 units of RNA polymerase (Boehringer Mannheim), 100 μ M each of GTP, UTP and ATP, 10 μ M [α -³²P]CTP (1.5 Ci mmol⁻¹) and RNA polymerase binding buffer (5% glycerol, 20 mM Tris-HCl pH 8.0, 10 mM MgCl₂, 0.1 mM EDTA, 0.1 mM DTT and 120 mM KCl) in a total volume of 20 μ l. After 10 min incubation at 37°C, 8 μ l of formamide-buffer electrophoresis dyes²³ supplemented with 0.4 μ g tRNA were added, and the samples were lyophilized to 8 μ l volume. A 6% acrylamide: bis (30:1) gel with 8 M urea was run²³ and autoradiographed overnight. The position of a 108-base transcript from ColE1²⁴ is indicated. L and S indicate long (340 bases) and short (41 bases) transcripts, respectively. The sources of the DNA fragments used were pNU6 (*ampP*⁺, *ampL*⁺) (lane a), pNU28 (*ampP15G16*, *ampL*⁺) (lane b) and pNU35 (*ampP15G16*, *ampL35A*) (lane c). B and C show autoradiographs of RNA sequencing gels of the long and short transcripts, respectively. The 5'-end-labelled transcripts were synthesized in RNA polymerase binding buffer supplemented with 150 μ M CTP and UTP, 40 μ M GTP, 40 μ M [γ -³²P]ATP (100 Ci mmol⁻¹) and 10 units RNA polymerase in a total volume of 100 μ l. The long transcript was synthesized with 2.2 μ g of the 1.3-kilobase *SmaI*-*SacII* fragment from pNU35 as template, and the short transcript with 1.25 μ g of the 1.5-kilobase *XhoI*-*SacII* fragment from pNU28. After incubation at 37°C for 15 min, the samples were treated as above except that the gel contained 8% acrylamide. The transcripts were isolated by the method of Maxam and Gilbert²⁵ and the RNA sequencing reactions were as described by Krupp and Gross²⁵. All reactions were done with 4 μ g of carrier tRNA. The G+A+U reactions were carried out with 5 and 50 μ g of *Neurospora* endonuclease, respectively, the A reactions with 0.05 and 0.5 units of RNase U₂, respectively, and the G reactions with 1 and 10 units of RNase T₁, respectively. H⁺ indicates controlled partial acid hydrolysis giving labelled mRNA of all sizes. L and S indicate untreated long and short transcripts, respectively. The position of the orange G and bromophenol blue markers which migrate with 2 and 6 bases length, respectively²⁶, on the 25% polyacrylamide-urea gels used is marked OrG and BPB. Note that due to the absence of a phosphate at their 3' ends, oligonucleotides produced by *Neurospora* nuclease move more slowly in the gel²⁵. These bands have been connected with the corresponding bands from the other reactions. The sequence of the transcripts is indicated between B and C. P indicates positions where the transcripts due to their secondary structure are protected from the action of the enzymes. D is an autoradiograph of a part of an 8% polyacrylamide gel, showing the sequence of the long transcript around the termination point of the short transcript. Note that in contrast to the transcripts, the labelled oligonucleotide degradation products have a phosphate at their 3' end. Consequently, when interpreting D it must be remembered that the untreated ladder is displaced upwards by about half a nucleotide unit. Most of the short transcripts terminate at base 41 of the long transcript with minor termination at base 43.

Fig. 4 Expression of β -lactamase in a coupled *in vitro* transcription-translation system. The system is originally derived from Zubay²⁷, and modified by Johnsen²⁸ and Collins²⁹. The polypeptides were separated on a 10–17.5% gradient polyacrylamide gel as previously described⁶. The gel was fluorographed using En³hance (NEN). The plasmids used were: a, pBR322; b, pNU6; c, pNU28; d, pNU35; e, no plasmid DNA added. The 36K and 38K proteins which represent mature β -lactamase and presumed precursor β -lactamase, respectively, are marked by arrows.

reveals that the long transcript contains seven times as many C residues as the short one. Taking this into account, and with the relative band intensities obtained by scanning of the autoradiographs, we conclude that the short transcript is reproducibly about 15 times more abundant than the longer one.

In vitro transcription with the same amount of the analogous DNA fragment from pNU28 (carrying the *ampP15G16* mutation) resulted in an increase in the synthesis of both the long and the short transcripts (Fig. 3A, lane b). This contrasts with the result obtained when the corresponding *SacII-XhoI* fragment from pNU35 (carrying both the *ampP15G16* and *ampL35A* mutations) (lane c) was transcribed; no synthesis of the short 41-base transcript was observed. Moreover, the amount of the long run-off transcript was increased. The loss of the short transcript associated with an increase in the amount of the long run-off transcript suggests that the second mutation in TE18, *ampL35A*, abolishes termination in the *amp* leader region.

Localization of initiation and termination points for transcription

The initiation nucleotide *in vitro* of β -lactamase mRNA was determined by transcription using 10 μ M of one nucleotide triphosphate (NTP) and 150 μ M of the other three NTPs. Synthesis of β -lactamase transcripts was severely inhibited by ATP limitation but not by limitation of any of the other three NTPs (data not shown). This suggests that A is the 5' nucleotide. The long run-off transcript and the short transcript were labelled

using [γ -³²P]ATP, and subjected to RNA sequencing by partial enzymatic degradation (Fig. 3B, C). The first 16 nucleotides in the two transcripts were identical and homologous to the DNA sequence from bases +1 to +16. This shows that the A at +1 is the start base for both these mRNAs and confirms the position for the β -lactamase promoter. The nucleotides in the RNA sequence between positions 17 and 37 except for the A and U residues at positions 27 and 28, respectively, were protected against enzymatic cleavage. As the enzymes used are specific for single-stranded RNA¹¹, this finding implicates the existence of a 9-base pair RNA stem with a 3-base loop at positions 26–28. The point of termination of the short transcript was determined by comparing the length of non-degraded short transcript with that of enzymatically degraded long transcript (Fig. 3D). At least 99% of the short transcript ended with the U at position 41. A minor fraction terminated two nucleotides later.

Expression of the *amp* operon in a coupled *in vitro* transcription-translation system

When DNA from plasmids pNU6, pNU28 and pNU35 were added to a coupled transcription-translation system a protein with an apparent molecular weight (MW) of 38,000 (38K) was produced. The relative production of this protein from the respective plasmids was ~1:15:60 (Fig. 4). Purified β -lactamase migrates with an apparent MW of 36K. A faint band appeared at this position in the gel when plasmid pNU6 was used. In the mutants the corresponding protein band was more intense. We suggest that the 38K protein observed is the precursor form of the *E. coli* chromosomal β -lactamase postulated on the basis of the DNA sequence. The uppermost band with an apparent MW of 56K also increased in intensity in the mutants—the nature of this band is not known.

The fourfold difference between plasmid pNU28 and pNU35 in production of the pre- β -lactamase in the coupled transcription-translation system, corresponds to the fourfold differences in steady-state levels of β -lactamase found *in vivo*. On the other hand, in the *in vitro* transcription system the difference in transcriptional readthrough was about 16-fold. This suggests that a factor(s) present *in vivo* and in the coupled

Fig. 5 A model for growth rate-dependent attenuation of transcription. The stippled area represents a ribosome. The symbols are the same as in Fig. 2B. A, terminated transcript; B, hypothetical protection by the ribosome preventing formation of the termination stem, leading to readthrough (see text for discussion).

system increases the transcriptional readthrough about fourfold compared with a pure *in vitro* transcription system.

Features of the β -lactamase attenuator

One of our major conclusions is that the *amp* operon contains within its leader region a site for termination of transcription that is recognized by the *E. coli* RNA polymerase *in vitro*. Factors such as the rho protein¹² are not required for efficient termination *in vitro* at this site. However, we do not know whether the rho protein has any effect in the *in vivo* situation. On the other hand, the terminator in the *amp* leader has a structure similar to those of sequenced rho-independent terminators¹⁰.

The base pair substitution *ampL35A* occurred 7 base pairs upstream from the major termination site and within the 9-base pair symmetrical DNA sequence (Fig. 2B). From both thermodynamic considerations and the relative susceptibility to enzymatic cleavage, we suggest that the leader RNA transcript forms a secondary structure with a 9-base pair G $\leftrightarrow$ C-containing stem and a 3-base loop (Fig. 5A). The *ampL35A* mutation decreases the thermodynamic stability of such an RNA stem from a ΔG value of -29.4 kcal to -17.4 kcal (ref. 13). Termination of transcription *in vitro* decreases to less than 1% in template with the *ampL35A* mutation. It seems likely that the terminator in the *amp* leader also operates *in vivo*, because β -lactamase synthesis at the maximal growth rate is roughly four times higher in the *ampL35A*-carrying mutant strain, TE18, than in its parent strain, LA51.

Growth rate-dependent regulation of *ampC* is exerted at the level of anti-termination

In the *trp*, *phe*, *his*, *leu*, *ilv* and *thr* biosynthetic operons, a potential coding region for a short leader peptide precedes a terminator¹⁴⁻¹⁶. In each case, the leader peptide contains 'regulatory' codons for the amino acids that regulate the operon. In the model originally put forward by Lee and Yanofsky¹⁷ it is proposed that synthesis of the leader peptide is involved in the regulation of transcription termination at the attenuator. This regulation depends on the formation of mutually exclusive RNA secondary structures. Ribosomes translating the entire coding region would permit formation of the terminator secondary stem and loop structure, whereas ribosomes slowed down at the 'regulatory' codons, due to a deficiency in the concentration of the charged cognate tRNA, would favour formation of an alternative structure and thereby preclude formation of the terminator structure.

The 41-base long *amp* leader transcript is considerably shorter than other known leader transcripts and has no potential coding region for a leader peptide. Moreover, the *amp* leader RNA cannot form any alternative secondary structure that precludes formation of the terminator stem and loop. However, examination of the RNA sequence reveals that the first three bases are complementary to a sequence near the 3' end of 16S rRNA (ref. 18). Furthermore, bases 8-13 consist of an initiation codon (AUG) that is followed directly by an ochre stop codon (UAA). Thus, the *amp* leader RNA has a potential ribosome binding site and may form a translation initiation complex. Our major concerns are whether or not this potential ribosome binding site is used and whether it could have a regulatory effect on the termination of transcription. A ribosome stalled at the stop codon would protect ~ 12 bases downstream¹⁹. As shown in Fig. 5B this could prevent formation of the termination stem and loop structure.

Expression from the *amp* operon is positively correlated with the steady-state growth rate. In theory, this growth rate-dependent regulation could occur at the level of initiation or

termination of transcription or both. The *ampP15G16* mutation increases transcription initiation *in vitro* by a factor of 15 without significantly affecting the degree of transcription termination. As this up-promotor mutation did not affect the growth rate-dependent expression of *ampC* we find it unlikely that the *amp* promoter participates in this regulation.

In the double mutant, TE18, expression of *ampC* has become independent of the growth rate. This fact, together with the observation that the mutation *ampL35A* abolishes termination of transcription *in vitro* at the *amp* attenuator, suggests that the growth rate-dependent regulation of the *amp* operon is exerted at the level of anti-termination. The anti-termination factor in our system is not known. We hypothesize that ribosome binding at the *amp* leader RNA has a regulatory role. The number of ribosomes per cell mass increases, over a broad range, proportionally with growth rate². If binding of ribosomes to the *amp* leader region is proportional to the cellular concentration of ribosomes, the degree of anti-termination would increase proportionally with growth rate.

Many proteins exhibit the same growth rate-dependent regulation as the chromosomal β -lactamase. For many operons this mode of regulation might also be exerted at the level of anti-termination. Terminator-like sequences have been found in the leader DNA of the *rpsE* and *rpsL* operons. From the *rpsL* operon, a short transcript has been obtained²⁰ which suggests that termination can at least occur *in vitro*. It is, however, not known if these possible terminator sequences are involved in the regulation of the operons.

The regulatory region of *ampC* consists of two control regions, a promoter and an attenuator. The up-promotor mutation described here changes the distance between the two conserved regions in the promoter. Possibly this is of importance for efficient RNA polymerase recognition. Because of the ease with which one can isolate and analyse mutations in the regulatory regions of the *amp* operon, this system can be used to increase our understanding of the functions of promoters and attenuators.

We thank Torbjörn Nilsson and Per Pettersson for help with the amino acid sequence determination, Monica Persson for technical assistance, and Stewart Cole, John K. Davies and Christopher Korch for careful reading of the manuscript. This work was supported by grants from the Swedish Natural Science Research Council (Dnr 3373) and from the Swedish MRC (Dnr 5428).

An extended source of H Ly α emission (1,216 Å) from the vicinity of Saturn has been detected previously by a rocket-borne spectrometer¹, the OAO-Copernicus satellite², and the Pioneer 11 spacecraft³. During the rocket experiment, in which Saturn was observed on 15 March 1975, 700 R $\pm$ 50% of Ly α emission was detected from the planet and an additional 200 R $\pm$ 50% from a 53 arc s diameter circular area centred on the planet. This additional emission was believed to emanate from the ring system. The Copernicus observations, carried out in April 1976 and April 1977, yielded Ly α intensities of 1.40 $\pm$ 0.45 kR for the saturnian disk, <100 R for the rings, and 200 $\pm$ 100 R for Titan's torus. During the Pioneer 11 Saturn flyby in August–September 1979, the long-wavelength channel UV photometer detected emissions from the planet, the vicinity of the rings, and the orbital path of Titan; these emissions were interpreted as resonant scattering of solar Ly α radiation by H atoms and possibly auroral Ly α emission from the planet. Several mechanisms for producing H atoms outside of Saturn's atmosphere have been proposed, including sputtering of water ice from the rings by magnetospheric charged particles⁴, 'photo-sputtering' of the ring water ice by solar UV radiation⁵, and escape of H atoms from Titan's atmosphere⁶. A more recent suggestion is the possible impact on the rings and subsequent neutralization of the protons from an extended saturnian ionosphere¹⁵. We report here a new investigation of these potential sources of Ly α emission in a series of observations of the saturnian system carried out between January and July 1980 using the short wavelength (SWP) spectrograph of the IUE Observatory^{7,8}. North–south maps of the Ly α emission across the planet disk have shown pronounced spatial asymmetries in emission brightness. These asymmetries vary markedly on a time scale of days and are interpreted as bursts of Ly α emission of as much as 1 kR brightness averaged over a 6 $\times$ 10 arc s area, above a constant planetary emission level of 700–800 R. In fact, the Ly α emission peaks appear as essentially point source features in these data: if the emitting region is smaller than the 6 $\times$ 10 arc s instrumental resolution, the surface brightness must be proportionally higher.

Spatial imaging with the IUE has been accomplished both in a series of exposures of different regions of the saturnian system and by sampling within the field-of-view of the large spectrograph entrance aperture in single exposures. The image of the field-of-view subtended by the aperture is focused directly onto the detector at each wavelength; because the angular resolution of the instrument is 5–6 arc s on planetary objects and the large aperture extends 10 $\times$ 23 arc s, imaging perpendicular to dispersion is possible in a single exposure. By moving the $\sim$ 16 arc s diameter image of Saturn 5–10 arc s between exposures along the major axis of the aperture (which is constrained to point roughly north–south), maps of the disk emission plus the background geocoronal and interplanetary Ly α emission immediately north and south of Saturn have been obtained with 6 arc s spatial resolution. In each of the exposures centred on the polar regions, therefore, the level of background Ly α is directly measured and subtracted from the planetary emission; in exposures centred on Saturn the background level has been

determined by matching the level of planetary emission to that observed in the polar exposures immediately preceding or following. A relative sensitivity correction in the direction perpendicular to dispersion has been derived from exposures of the background Ly α emission and applied to the data reported here. The error in applying this correction has been determined by testing it on other exposures of background Ly α emission and measuring the average deviation from the mean level of emission; this error is $\pm$ 200 R. The pointing of the spacecraft during the north–south maps has been determined by noting the position in the aperture of the sharp drop in grating-scattered long wavelength radiation at the northern and southern edges of the saturnian disk. The north–south positioning of the aperture is believed to be accurate to within 1–2 arc s. This same technique of north–south mapping has been used in observations of the polar auroral Ly α emission from Jupiter⁹.

Representative north–south maps of the Ly α emission are plotted in Fig. 1 from observations performed on 19 January, 5 May and 22 July (all 1980). Non-equatorial peaks in the emission are apparent in the data from the first two days, while the July data are symmetric north–south with an equatorial brightness of 800 R. This equatorial brightness in the individual exposures on 22 July was measured over one-half of a rotation of the planet; therefore, 700–800 R is interpreted as a constant level of planetary emission from Saturn's upper atmosphere. The data of 22 July provide a good fit to a model emission profile

Fig. 1 North–south maps of the H Ly α emission from Saturn plus sky background. Different point characters represent different camera exposures, and the $\pm$ 200 R error bars are discussed in the text. The measured background varied by as much as $\pm$ 500 R in a series of exposures, and the exposures plotted have been normalized to the same level of background (set at the average background level observed on a given day). *a*, 19 January 1980; *b*, 5 May 1980; *c*, 22 July 1980.

§ Permanent address: Joint Institute for Laboratory Astrophysics and Laboratory for Atmospheric and Space Physics, University of Colorado, Boulder, Colorado, USA.

Fig. 2 Observing geometry during the exposures of 19 January 1980. The dashed line and arrow indicate the line-of-sight from the Earth, and the solid line represents the ring plane (which is tilted 1.6° south of the line-of-sight). The enhanced $\text{Ly}\alpha$ emission observed apparently from the south pole of Saturn could actually have come from anywhere in the shaded region. Roman numerals indicate the orbital radii of Saturn's inner moons (VI is Titan).

(the solid line in Fig. 1) representing a uniformly emitting disk of 800 R brightness smoothed by the 6 arc s instrumental resolution. Note that the decrease in emission from the equator to the poles in the model profile is due to the spatial resolution of the instrument, not limb darkening. If this emission is completely produced by resonant scattering of solar $\text{Ly}\alpha$ from upper atmospheric H it corresponds to an H column abundance on the order of 10^{14} cm^{-2} , following the simple resonant scattering model for Jupiter outlined by Clarke *et al.*¹⁰. This model assumes an exospheric temperature of 1,200 K, a solar flux at line centre at the Earth of $5.14 \times 10^{11} \text{ photons cm}^{-2} \text{ s}^{-1} \text{ \AA}^{-1}$ (ref. 11), and no absorption by interplanetary H along the path to and from Saturn. The assumed temperature value is uncertain, but 1,200 K is consistent with the Pioneer 11 radio occultation data¹². A disk-averaged $\text{Ly}\alpha$ intensity of 700–800 R implies that a homopause value of the eddy diffusion coefficient is in excess of $10^7 \text{ cm}^2 \text{ s}^{-1}$. Uncertainties about the role of particle precipitation and the methane density distribution and temperature structure of the mesosphere and thermosphere prevent an exact calculation of the eddy diffusion coefficient at this time. Interplanetary absorption of $\text{Ly}\alpha$ on the round trip to Saturn has been modelled by Bertaux *et al.*¹³, who predict 40% absorption at the time of these observations; thus, Saturn's $\text{Ly}\alpha$ emission could be significantly brighter as measured by a spacecraft in the vicinity of the planet. An H column of 10^{14} cm^{-2} is optically thick and Saturn should exhibit limb darkening at $\text{Ly}\alpha$; however, with the existing spatial resolution it is not possible to distinguish between a cosine darkening function and a uniformly emitting disk. Note that the points plotted in Fig. 1 represent average brightness over an area extending 10 arc s in the east-west direction; assuming a cosine darkening east-west (as well as north-south), the actual sub-solar point brightness would be ~5% higher than that measured.

Exposures were also taken of Titan near western elongation on 5 May 1980, of the sky background 4 arc min north of Saturn on 9 May 1980, and of the region of the outer rings 20 arc s east of the centre of Saturn on 9 May 1980. To within ± 200 R no $\text{Ly}\alpha$ emission above the level of sky background was detected from either Titan or the rings, although the ring exposure was taken on a day when no bursts of $\text{Ly}\alpha$ emission above the 700–800 R level were detected on the saturnian disk. The additional sky background exposure was taken to check for a possible extended H atmosphere around the saturnian system, as hypothesized by McDonough and Brice⁶; however, the background brightness 4 arc min north of Saturn was the same within ± 200 R as that measured immediately north and south of Saturn in the preceding and following exposures. All exposures to date are listed in Table 1, specifying the target area, the longitude of the central meridian of Saturn, the tilt angle of the ring plane north or south of the line of sight from Earth, and the observed level of emission above the 700–800 R planetary level. The longitudes listed are in the Saturn longitude system (λ_{SLs}) defined by the recent observations by the Voyager Planetary Radio Astronomy Group¹⁴. A comparison was also made between the data in Table 1 and the occurrence of radio emission from Saturn, but no direct correlation was discovered.

Unfortunately, the angular resolution of the IUE is not sufficient to pin down the source of the enhanced $\text{Ly}\alpha$ emission.

The excess emission from the southern half of the saturnian disk observed on 19 January, for example, could have originated anywhere along the shaded region shown in Fig. 2 and satisfied our viewing constraints. However, because the rings were within $\pm 2^\circ$ of being edge-on to the Sun throughout these observations and the $\text{Ly}\alpha$ bursts were variable on a time scale of days, it seems unlikely that photo-sputtering of ring particle ice is a plausible source mechanism for these bursts. In addition, <200 R of $\text{Ly}\alpha$ emission was seen from the vicinity of Titan on the same day that a burst of brightness 600 R was detected from the northern half of the saturnian disk, implying that the source of this enhanced emission was not Titan or an associated torus. The most plausible production mechanisms seem to be either: (1) aurora in Saturn's upper atmosphere or (2) a cloud of H atoms in the vicinity of the rings which are released by charged particle sputtering and radiate through resonant scattering of solar $\text{Ly}\alpha$ radiation (and possibly through charged particle excitation). More accurate knowledge of the source of these bursts of $\text{Ly}\alpha$ emission requires better spatial resolution and more flexibility in the angle of view, as will be available from the Voyager 1 and 2 spacecraft now approaching encounter with Saturn.

Table 1 Observations of H Ly emission from Saturn

Date (1980)	Target	Ring plane tilt angle	λ_{SLs} (CML)	Average background level (kR)	Emission above model level (R)
19 January	5° S	1.6° S	319°	1.5	+900
	5° S	1.6° S	346°	1.5	+900
	5° N	1.6° S	34°	1.5	—
12 March	8° N	0°	306°	2.5	—
	Centre	0°	338°	2.5	—

Mechanical aggregation of enstatite chondrites from an inhomogeneous debris cloud

C. A. Leitch & J. V. Smith

Department of the Geophysical Sciences, University of Chicago, Chicago, Illinois 60637, USA

Enstatite chondrites have oxygen isotope ratios closer to those of the Earth and Moon than other meteorites. Their minerals are chemically reduced; metal contains Si, and some Ca, Ti, Mg and Mn are incorporated in sulphides rather than silicates. Clinostatite and olivine are virtually Fe-free^{1,2}. We have reported³ two types of clinostatite in the Indarch enstatite chondrite, one luminescing blue and one red. Similar clinostatites in the Kota-Kota enstatite chondrite are associated with two distinct types of forsteritic olivine, one luminescing orange and the other blue. The textural relations and differences in chemical composition cannot be explained by progressive condensation from the solar nebula and require the mechanical mixing of material from at least two sources. We suggest here that enstatite chondrites result from mechanical and chemical processes during aerodynamic sorting and gravitational settling of debris from a hot cloud of dust, liquid and gas produced during collision of planetesimals.

Kota-Kota, like Indarch, contains four types of clinostatite-rich chondrules: porphyritic > fine-grained > barred > radiating. One radiating chondrule composed primarily of SiO₂ was observed. A luminescence microscope revealed distinct red and blue clinostatite grains, as well as orange and blue olivine grains. The latter were not found in the first thin section of the Indarch chondrite³, but a few orange and blue grains were found in six new sections. Porphyritic chondrules are extremely

complex and a single chondrule may contain all four phases (Fig. 1). Red clinostatite grains may enclose blue clinostatite, orange olivine and/or blue olivine, while individual blue clinostatite grains may enclose orange and/or blue olivine. Red clinostatite was not observed inside blue clinostatite. Fine-grained chondrules contain blue clinostatite and rare blue olivine. Both barred and radiating chondrules are composed predominantly of lamellae of either red or blue clinostatite. All chondrule types are surrounded by a shell composed of a fine-grained mixture of all minerals found in the meteorite. Similar shells were found surrounding chondrules in Indarch³ and in ordinary chondrites⁴.

Electron microprobe analyses were obtained with an ARL-EMX instrument. Magnesium, Si and Fe were determined with a solid state detector at 15 kV, 0.1 μ A and 120 s live time. Minor elements were determined with crystal spectrometers and 25 kV and 2 μ A. Counting times were selected for peaks and backgrounds to achieve a precision near 30 p.p.m. (1 σ) for individual analyses. Standards were: Ca₂P₂O₇(P), Di₈₅Jd₁₅(Ca, Al, Na), Corning glass V(Ti, Cr), Corning glass W(Mn) and Corning glass X(Ni).

As for Indarch³, minor element contents correlate with luminescence colour and not with chondrule type. Representative analyses in Table 1 are taken only from the chondrule in Fig. 1. Table 2 shows observed ranges in minor element contents for both olivine and clinostatite. Red clinostatites have

Fig. 1 Schematic representation of a porphyritic chondrule. Black, clear, hatched and stippled areas are respectively, orange olivine, blue olivine, red clinostatite and blue clinostatite. Blue clinostatite is polycrystalline, but individual grain boundaries are not shown. The chondrule is 410- μ m wide.

higher concentrations of Ti, Al, Cr, Mn and Ca, whereas blue ones have higher Na. Orange olivines contain more Cr and Mn than blue ones.

The method of assignment of valence states to minor elements in the pyroxenes has been detailed elsewhere³. There is insufficient Al and Cr³⁺ in blue clinostatite to balance the observed Na, and some Fe must be assigned to the trivalent state to maintain charge balance if a defect-free MTO₃ formula is assumed. For red clinostatites, it was again necessary to assume that some Fe³⁺ is present to obtain a cation: oxygen ratio fitting the theoretical value of 2:3. For clinopyroxene analyses in columns 3 and 4 of Table 1, it is necessary to assume that 38 and 8%, respectively, of total Fe is present as Fe³⁺. However, a wet chemical analysis of a pyroxene separate from Kota-Kota⁵ showed only 0.03 wt % Fe₂O₃ against 0.93 wt % FeO. The trivalent Fe was attributed to terrestrial oxidation, and the significance of the recalculation of the electron microprobe analyses is unclear. If some or all of the Cr were divalent, even more Fe³⁺ would be required.

The observed textures and bimodal chemical compositions of the olivines and clinostatites rule out formation of these meteorites by direct condensation from the solar nebula. Mechanical aggregation of material from at least two source regions is needed to explain the blue and red varieties, and the

observed textures indicate a complex sequence of events. Enclosure of rounded olivine grains by pyroxene grains suggests that olivine formed earlier than clinoenstatite in agreement with condensation calculations for a solar nebula with either the solar C/O ratio of 0.57 (ref. 6) or the higher ratio of ~1.0 postulated⁷ to explain enstatite chondrites.

Clinoenstatite melts incongruently at 1,557 °C to form forsterite plus liquid⁸. Because the forsterite bodies are rounded rather than euhedral, it is unlikely that the forsterite observed in Kota-Kota was so formed. In addition, both orange and blue olivine occur surrounded by red or blue pyroxene. Because forsterite melts at a much higher temperature (1,850 °C) than enstatite, pre-existing forsterite might have survived the melting of clinoenstatite.

The simplest scheme to be considered for the Kota-Kota meteorite involves (1) progressive condensation of two separate

regions of the solar nebula to give minor forsterite and dominant clinoenstatite, and (2) mechanical mixing of the condensates. Because this scheme is insufficient to explain the textural properties of the chondrules, some other process or processes must be involved. In view of evidence^{9–11} for accretion of planets through planetesimals, generation of chondrules during collision of planetesimals is considered¹².

The similar ranges of clinoenstatite compositions in Table 2 indicate that the Indarch and Kota-Kota meteorites may have come from the same parent body. Orange olivine and red clinoenstatite are assumed to derive from the same condensation region because of comparable Cr₂O₃ and MnO contents, and similarly the blue olivine and blue clinoenstatite are paired. Enclosure by red clinoenstatite of blue clinoenstatite, orange olivine and blue olivine rules out mechanical mixing of crystals that condensed in equilibrium conditions in two source regions before planetesimal collision. To explain the textural relations it seems that at least some red clinoenstatite must have crystallized after the other three minerals. Because there is a sharp discontinuity in luminescence and chemistry between adjacent grains of porphyritic chondrules (Fig. 1), it seems that an enclosing grain grew without reaction with an enclosed grain. Figure 2a–d shows how the porphyritic chondrules may have formed, partly by mechanical aggregation of pre-existing crystals and partly by growth of red clinoenstatite around pre-existing crystals. A liquid stage for at least some red grains seems necessary to explain the inclusion of blue clinoenstatite and orange and blue olivines, and it may prove necessary to introduce additional steps of crystallization and mechanical disaggregation. Interstices between aggregated crystals are assumed to be filled by dust and vapour deposits.

Barred, radiating and fine-grained chondrules are assumed to have derived from liquids formed during planetesimal collision. Because these droplet chondrules are composed predominantly of either red or blue clinoenstatite with only minor amounts of interstitial phases, it is necessary to postulate formation of two separate liquids with compositions near those of the red or blue clinoenstatites. Such liquid droplets could then incorporate minor amounts of pre-existing solid material released by mechanical disaggregation of the colliding planetesimals (Fig. 2e–h). The impact melts are assumed to have been dispersed by high velocity jets¹³ produced during collision. Such jets must

Fig. 2 Schematic representation of chondrule formation from a gas-dust-liquid droplet cloud. Angular shapes are crystals; circles are liquid. a–d shows the formation of a porphyritic chondrule: a, some blue enstatite, blue olivine and orange olivine becomes surrounded by red liquid; b, red liquid forms crystals enclosing blue enstatite, blue olivine and orange olivine; c, crystals become aggregated and a porphyritic chondrule similar to that in Fig. 1 is formed; d, chondrule becomes surrounded by a shell of fine-grained dust. e–h shows the formation of a barred chondrule with an olivine inclusion: e, blue liquid droplet comes in contact with an orange olivine; f, olivine is trapped inside blue liquid droplet; g, liquid crystallizes and assumes a typical barred appearance; h, chondrule becomes surrounded by a shell of fine-grained material.

have dispersed the molten material quickly enough to prohibit mixing between the two liquids.

In such a scheme, the massive debris from the collision is assumed to coalesce into a new planetesimal in part of which melting and high-grade metamorphism would occur¹². Smaller fragments would remain in orbit, and later fall onto the surface. Dodd¹⁴ has given evidence for aerodynamic sorting of chondrules in ordinary chondrites⁴. He argued in favour of continuous entry of particles into an atmosphere because gas drag in a stagnant atmosphere would produce a graded deposit on the surface of a growing planetesimal. However, shock waves produced in a gas-dust cloud by incoming bodies from colliding planetesimals may have caused material to settle rapidly into an ungraded deposit¹².

Although details still need to be worked out, it seems certain

that enstatite chondrites are not direct products of the solar nebula. In spite of the complexity of the mineralogy and petrography, we need not abandon the well-documented mixing models for the bulk compositions of unequilibrated enstatite^{15,16} chondrites, at least as a first approximation. Provided that little material was lost to the solar nebula during collision, the bulk chemistry of chondrites should be explicable in terms of direct condensates that entered the original planetesimals. Although the present scheme applies specifically to enstatite chondrites, the general features may also apply to the unequilibrated ordinary chondrites^{17,18}.

Porous anodic film formation on aluminium

G. E. Thompson & G. C. Wood

Corrosion and Protection Centre, University of Manchester Institute of Science and Technology, Manchester M60 1QD, UK

The development of porous anodic films on aluminium in the major forming acids has been established¹⁻⁵. However, little information has been provided to explain the markedly different rates of steady-state film growth for anodizing in constant voltage conditions in these acids, with the anodic film cell parameters dependent on the cell voltage¹. The regular cellular morphology of the steady-state films and the substructure developed in the forming acids are revealed in Fig. 1. The characteristic parallel-sided pores, at the centres of approximately hexagonal cells, pass normal to the macroscopic metal surface but are separated from it by the barrier layer. Here, from considerations of the film material substructure and the distribution of species within the film derived from the forming acid, it is postulated that the likely variations in the local field strengths across the barrier layers can explain the steady-state anodizing behaviour observed in the different acids in constant voltage conditions.

Direct transmission electron microscopy of ion-beam thinned steady-state porous anodic films, formed originally in phosphoric or oxalic acid, has shown the presence of cell boundary bands separated from the electrolyte in the pores by differently textured film material⁶ (Fig. 1). Microanalysis of the regions comprising the cell material of the film formed in phosphoric acid suggests that the cell-boundary band is composed of virtually pure alumina, whereas phosphorus is detected in the adjacent differently textured material⁷. For films formed in chromic acid, no significant chromium is detected in the cell material⁵, which appears similar in nature to the cell boundary band material observed for films formed in phosphoric acid, that is, relatively pure alumina. The highly acid anion contaminated films formed in sulphuric acid also show a region of relatively pure alumina which is not resolved readily in the electron microscope for the films formed at the usual low voltages (R. Ozcan and our unpublished work). From such knowledge it is possible to depict the barrier layers of the films formed in the major anodizing acids in terms of the ratio of the thicknesses of

relatively pure alumina region to acid anion-contaminated material, which seems to increase in the order: sulphuric acid (0.05) > oxalic acid (0.1) > phosphoric acid (0.5) > chromic acid (∞).

The relative extents of the different regions present in the barrier layers of the films formed at constant voltages in the usual anodizing conditions in the above acids are illustrated in Fig. 1, which shows that the films form at relatively similar nm V⁻¹ ratios. The relatively pure alumina is drawn as a solid region as it is thought that this more compact film grows by ionic migration to form a glassy or anion-free microcrystalline structure, whereas the outer microcrystalline acid anion-contaminated film material is deposited under the field from initially colloidal alumina⁸. Different extents of deposition explain the varying current efficiencies observed in the corresponding acids.

There is a direct link between the above findings and the rates of formation of the films in the different anodizing acids, at constant voltage. For films formed at 20 V, typical rates of formation increase in the order: sulphuric acid > oxalic acid > phosphoric acid > chromic acid.

For example, the rate of formation of the film in sulphuric acid, with the thinnest relatively pure alumina region, is much greater than in chromic acid, where films composed of relatively pure alumina are formed. Furthermore, the current density (i) is related to the potential drop (V) across the barrier layer by the high field conduction theory:

$$i = A \exp (BV/d)$$

where A and B are constants, for a given temperature, and d is the overall barrier layer thickness. In the above equation V/d represents the effective average field across the barrier layer which is approximately constant for the barrier layers of the different films because the measured nm V⁻¹ ratios are similar. However, if the true field across the relatively pure alumina region of the barrier layer is in the order: sulphuric acid > oxalic acid > phosphoric acid > chromic acid, because this represents the order of increasing thickness of the observed cell boundary bands, then the rates of formation of the films in the different acids will also vary in the order given above if solid state ionic migration across the inner layer is the rate-determining step. The passage of ions through the outer regions of the contaminated film is thought to proceed relatively easily. Thus, during anodizing in the major anodizing acids, the field strength is thought to be greater across the inner, compact relatively pure

Fig. 1 The plan and sectional views of a pore and adjacent cell for films formed in each of the major acids: *a*, sulphuric acid; *b*, oxalic acid; *c*, phosphoric acid; *d*, chromic acid. The cell comprises acid anion-contaminated film material adjacent to the pore and relatively pure alumina remote from it: □ acid anion contaminated film material; ■, relatively pure alumina.

alumina region and lower across the acid anion-contaminated alumina film, which probably varies from solid in contact with the cell boundary bands to gel-like material at the base of the pores. Microporosity or relatively easy passage of ions through intercrystallite pathways will reduce the effective field further. Figure 2 shows how the total voltage drop across the barrier layer is similar for the highly contaminated film formed in sulphuric acid (Fig. 2a) and the acid anion-free film formed in chromic acid (Fig. 2d) where the cell boundary band to contaminated film material ratios approach 0 and ∞ , respectively. The current density is higher in the former case because of the higher voltage drop across the pure alumina region adjacent to the metal interface. In addition, anodizing in chromic acid proceeds at relatively low current efficiency. In phosphoric and oxalic acids there are two zones. The voltage drop and field across the pure cell boundary bands are high but low in the outer acid anion-contaminated film material (Fig. 2b, c).

The variation in voltage drop across the adjacent film regions comprising the barrier layer is important and has been considered by Dell'Oca and Young⁹ in an investigation of the

different layered barrier film formed on tantalum in phosphoric acid. They suggested that a high field operates in the contaminated layer adjacent to the solution where phosphate reduces the permittivity and decreases ionic mobility. The case for a dependence of field strength on film thickness (for thin films) has been put forward by Dignam¹⁰. Here the different field strengths have been based on the likely mechanisms of film growth during steady-state porous film formation involving solid-state ionic migration across the relatively pure alumina region and deposition of the outer layer from a hydrous metal oxide solution. Direct observations of the film materials, revealed by ultramicrotomy of both barrier and porous-type anodic films, show the sections to be relatively uniform and featureless^{2,3,8,9,11}, only revealing telling changes after exposure to the electron beam¹⁰. This is thought to represent 'drying out' and/or ageing of the film material after anodizing, and it is only during anodizing that the variation in field strengths across the barrier layer is manifested. As the nm V^{-1} ratios for the different films have been determined after anodizing in the absence of the field it is not surprising that they show relatively similar values.

Fig. 2 Distribution of the voltage drop and field (the slope of the voltage-distance plot) across typical barrier layers of porous anodic films formed in each of the major acids: *a*, sulphuric acid; *b*, oxalic acid; *c*, phosphoric acid; *d*, chromic acid. The voltage drop is greatest and linear across the inner compact relatively pure alumina region and lower across the outer acid anion contaminated film material, where the voltage decreases progressively towards the film-solution interface. Consequently, the highest field is across the least extensive relatively pure alumina region, evident for the films formed in sulphuric acid, decreasing for the films formed in oxalic and phosphoric acids respectively, and lowest for the most extensive pure alumina region present in the films formed in chromic acid. The rates of formation of the corresponding films decreases in the same order.

The nature of the incorporated acid anion will probably strongly influence the size distribution of the deposited and contaminated microcrystalline alumina¹², and its hydrogen bonding characteristics, which affect the effective compaction of this material.

Thus, the steady-state anodizing behaviour of porous anodic films formed in the major anodizing acids can be related to the distribution of the acid anions within the barrier layers and the true field strengths across the relatively pure alumina regions. The effect of the acid anion on thermally enhanced field-assisted dissolution, or other processes whereby the relatively pure alumina region transforms to the acid anion-incorporated material and its influence on anodizing at constant current density, will be discussed elsewhere.

Tasmanian tree rings belie suggested anthropogenic $^{13}\text{C}/^{12}\text{C}$ trends

R. J. Francey

CSIRO Division of Atmospheric Physics, Aspendale, Victoria, Australia 3195

Published measurements in tree rings¹⁻¹⁰ suggest a persistent decrease with time of the ratio $^{13}\text{C}/^{12}\text{C}$, particularly in the period 1860-1940, and the release of C^{13} -deficient CO_2 from both fossil fuel combustion and forest clearing have often been invoked to explain the decreases. Freyer¹¹ concludes that "the existing measurements leave no doubt that the ^{13}C content in the cellulose fraction of modern wood was indeed decreased significantly". Data presented here for two tree species from sites with contrasting ecologies on the remote and exposed Tasmanian west coast do not, however, support claims that these trends, which have been observed in (mostly) Northern Hemisphere trees, are the global response of the atmosphere to agricultural and industrial activities.

Freyer's statement requires qualification. There is evidence^{2,4,7-9} of a levelling or an increase in $^{13}\text{C}/^{12}\text{C}$ ratios after 1940, moreover the period before 1860 is poorly sampled, thus the statistical significance of a modern trend over several decades is difficult to assess. The Freyer's conclusion is based

§ T. Bird (CSIRO Division of Forestry).

largely on trees of mid-latitude Northern Hemisphere origin, close (in a global sense) to major anthropogenic sources of CO_2 and associated pollutants¹², embedded in large natural seasonal variations in atmospheric CO_2 , and remote from major exchange reservoirs in the southern oceans.

The further step of relating a tree ring derived $^{13}\text{C}/^{12}\text{C}$ trend to the global CO_2 budget presents its own problems⁹, including (1) ignorance of the physical factors influencing $^{13}\text{C}/^{12}\text{C}$ in cellulose, sometimes creating large differences in cellulose of similar age from different locations within a tree, (2) the influence of local environmental factors, and (3) the relative insensitivity of $^{13}\text{C}/^{12}\text{C}$ in the atmosphere–biosphere–ocean system to gradual changes in the biosphere.

The forests of the Tasmanian west coast offer many advantages in the search for a global perspective on the carbon dioxide history of the atmosphere. The area is predominantly wilderness, remote from large scale industry and exposed to the almost circumpolar ocean fetches of the 'roaring forties'. Seasonal variations in the atmospheric CO_2 concentration are less than a tenth of those at high northern latitudes¹³. The native flora includes several species suitable for ring-width dating^{14–16} and living trees of great age, in stable ecosystems, are available.

Results are now available from the first seven trees analysed, whole wood analyses from three of which have been reported elsewhere^{17,18} and the temperature correlations reported there, while still evident at reduced magnitude, do not conflict with the cellulose results reported here. In what follows, comparisons will be made with measurements on cellulose^{1,3,4,8,9} (though similar conclusions would come from consideration of whole wood analyses^{2,4,7}).

The trees are referred to by their collector's designation, and relevant properties are summarized in Table 1. Full details of the trees and the analyses techniques will be given elsewhere¹⁹. The analysis repeatability on a homogeneous wood sample is typically 0.06‰.

On two of the trees, JR39 and BH858, comparisons have been made of $^{13}\text{C}/^{12}\text{C}$ variations along different radii. Analyses on 5-yr blocks of four radii for JR39 are shown in Fig. 1a, the inset shows the radii cut from a disk.

This record shows sharp discontinuity in $\delta^{13}\text{C}_{\text{PDB}}$ occurring at around 1869, where scarring suggests fire damage. After 1869 there is a corresponding sharp increase in ring width. The $\delta^{13}\text{C}_{\text{PDB}}$ and ring width increases are probably the result of sudden exposure of a sub-canopy sapling to free atmosphere, removing limiting factors related to competition, and/or markedly reducing the uptake of ^{13}C depleted respired carbon dioxide²⁰. It suggests that variations in $\delta^{13}\text{C}$ after this event were not seriously influenced by these factors.

While $\delta^{13}\text{C}_{\text{PDB}}$ varies by up to 1‰ in different radii, these differences are generally maintained throughout the adult life of the tree. In the context of possible large monotonic trends¹¹, this is taken as evidence (with some caution⁹) that trends representative of the whole disk can be inferred from one radius.

This application when only one radius is available is supported by Fig. 1b, showing three cores from tree BH858. The data are analysed in 10-yr blocks. Radius A is a core from a south-west direction, 1.09 m from the base; C is a north-east core from 0.58 m and D a south-east core from 0.81 m. Although a relatively young rainforest tree, there is no juvenile effect. It may be relevant that it is located on a small (~100 m diameter)

Fig. 2 $^{13}\text{C}/^{12}\text{C}$ analyses on all seven trees. Averages of the different radii are used for JR39, BH858. (Dashed lines indicate values corresponding to periods of marked ring width discrepancies.)

Table 2 Comparison of $\delta^{13}\text{C}$ trends since 1950

Medium	Period of data	Regression coefficient (% yr ⁻¹)	Ref.
Atmosphere	1956–1978	-0.030	21, 22
Cellulose	1950–1972	-0.018 ± 0.008	3
Cellulose	1950–1972	+0.042 ± 0.011	9
Cellulose	1951–1974	-0.005 ± 0.008	This work (6 tree averages)

exposed island in Bathurst Harbour (separated by 15 km of water and grassed hills from the open ocean), and flushing of respired sub-canopy CO_2 should be much more efficient than in a land-locked, heavily vegetated area.

Figure 2 shows an average curve for each of these trees, the remaining five curves referring to a single radius per tree. Four of these trees (SC15, SC19, SA, S3) are from a rainforest on a mountain ridge well exposed to the south-west, but 90 km from the coast. Three had germination dates estimated at about 1700 (although samples relating to a briefer period were provided for analysis) and were probably well exposed to free atmosphere from 1800. SC15, however, is much older with an estimated germination about 1090. Ring width data indicate a severe setback in growth from 1907 to 1917. In blocks after 1907, $\delta^{13}\text{C}_{\text{PDB}}$ values are on average about 1‰ more negative than immediately before 1907. At the time of sampling SC15 was lying on the ground and the tree may have fallen (had achieved a sub-canopy status) as early as 1907.

There is no possibility of canopy influences over the past several hundred years for MR3.4: estimated germination precedes 1450, and the high altitude, stunted 'krumholtz' form is evidence of its isolation and extreme exposure.

Figure 3 shows the combined data although the first 30 yr of JR39 analyses and the last 50 yr of SC15, (indicated by dashed lines in Fig. 2) for which independent ring width evidence suggest sub-canopy influences, are excluded. SC15, SC19, MR3.4 have common records between 1740 and 1905; and in Fig. 3a averages (in 10-yr blocks) of their deviations from the 1740–1900 mean are shown.

Six trees have common records between 1890 and 1970, and five of these extend back to 1870. Figure 3b shows averages (in 10-yr blocks) of their deviations from the 1890–1970 means (using five trees before 1890 and six trees thereafter).

In the context of global changes in atmospheric $\delta^{13}\text{C}$, the average of the six trees in Fig. 3b exhibits a striking lack of systematic behaviour—the data for a 10-yr interval never deviate significantly from the 1870–1970 mean. This contrasts with

Fig. 3 Combined $^{13}\text{C}/^{12}\text{C}$ data from 10-yr blocks. *a*, The average and standard deviation of deviations from the 1740 to 1900 mean for SC15, SC19, MR3.4. *b*, The average and standard deviation of deviations from the 1890–1970 means for SC19, MR3.4, JR39, BH858, SA and S3; for the period 1870–1890 only BH858 is not represented.

the steady decrease of about 0.5‰ (from 1870 to 1960) of Freyer¹¹.

A large decrease in $\delta^{13}\text{C}$ of almost 1‰ between 1840 and 1920 of Freyer¹¹, frequently interpreted as a global atmospheric response to a large net transfer of CO_2 from the biosphere^{5,6,8}, is not supported by the results in Fig. 3a. Clearly Fig. 3 and Freyer's results, for example, cannot both represent global atmospheric $^{13}\text{C}/^{12}\text{C}$ behaviour.

All Northern Hemisphere cellulose data are not incompatible with the Tasmanian results; over the same 1870–1970 period of Fig. 3b, the mean curve of Tans and Mook⁹ (and the whole wood data of Farmer⁷ and Galimov⁴) show a similar absence of a monotonic trend.

The data of Keeling *et al.*^{21,22} provide a useful comparison with the above results. They report annual average values of $\delta^{13}\text{C}$ and μ (the total CO_2 concentration);

$$1956 \mu = 314.1 \text{ p.p.m.} \quad \delta^{13}\text{C} = -6.69\text{‰}$$

$$1978 \mu = 334.2 \text{ p.p.m.} \quad \delta^{13}\text{C} = -7.34\text{‰}$$

representing a $\delta^{13}\text{C}$ change of -0.6‰ over 22 yr, or -0.030‰ yr⁻¹ for a linear trend.

Table 2 shows the available individual measurements of $\delta^{13}\text{C}$ in cellulose from 1950 linearly regressed against time. The anticipated atmospheric $\delta^{13}\text{C}$ response to fossil fuel combustion alone⁹ suggests that a linear approximation is reasonable over this period, and that the Table 2 regression coefficients (plus standard errors) are directly comparable.

Assuming the results obtained by Keeling *et al.*²¹ represent an ubiquitous $\delta^{13}\text{C}$ trend in the free atmosphere (supported by their comparison of North American and South Pole $\delta^{13}\text{C}$ measurements in 1978), then only the Rebello and Wagener tree can have responded in a direct manner.

The differences between $^{13}\text{C}/^{12}\text{C}$ trends in trees from different regions, coupled with the differences between most $^{13}\text{C}/^{12}\text{C}$ trends in tree-rings representing the past 20 yr and the direct atmospheric measurement, seriously question the interpretation of any tree record in terms of global atmospheric behaviour, and in particular the implicit assumption of constant fractionation in the atmosphere-biosphere exchange. An explanation involving large scale modification of atmospheric $^{13}\text{C}/^{12}\text{C}$ ratios as a result of plant respiration²³, apparently conflicts with well known rates of mixing of CO_2 in the atmosphere²⁴ during photosynthesizing hours. A solution must be sought in the mechanism of fractionation in plants.

I thank Dr Don Adamson, Dr John Ogden, Trevor Bird and George Dolezal for dated timber and detail on the individual trees, John Ogden and Drs Graeme Pearman and Paul Fraser for discussions, and Geoff Richards for the bulk of the chemical preparation.

Note added in proof: With respect to the suggestion²⁵ that isotope variations might primarily reflect ring width changes, there is a general absence of correlation between $\delta^{13}\text{C}$ and ring width in these trees, apart from exceptions mentioned in the text.

Ixtoc 1 oil spill: flaking of surface mousse in the Gulf of Mexico

John S. Patton & Mark W. Rigler

Department of Microbiology, University of Georgia, Athens, Georgia 30602, USA

Paul D. Boehm & David L. Fiest

Energy Resources Co. Inc., 185 Alewife Brook Parkway, Cambridge, Massachusetts 02138, USA

The blowout at the Ixtoc 1 offshore oil rig in the Gulf of Mexico (19°24' N, 92°12' W) produced a major oil spill. An estimated 140 million gallons of oil escaped before the well was finally capped¹; this compares with a spill of 66 million gallons of oil from the tanker *Amoco Cadiz*^{2,3}. In contrast to the rapid, close-to-shore release of the tanker's cargo, the Ixtoc 1 well released oil for 9 months into the open ocean where winds and currents dispersed the floating mousse (a light brown and orange water-in-oil emulsion) which had formed at the wellhead. Two and a half months after the blowout the western boundary current in the Gulf of Mexico^{4,5} had brought mousse to the American shore. An ultra-thin sheen also formed from the oil and was visible as a smoothness of sea-surface texture relative to the slightly rougher unpolluted waters. We report here that at a distance of 750–1,000 km from the well, Ixtoc 1 mousse occurred on sheen-covered sea surface primarily as gramme-sized pancakes and milligramme-sized flakes. Relative to pancakes, flakes were more dense, depleted in aliphatic compounds and enriched in polar compounds. Both particles were covered with a brittle 5–10 µm skin. Pancakes, skin, flakes and surface sheen seem to represent the four macroscopic component parts of a pelagic weathering cycle of Ixtoc 1 mousse.

Samples were collected from three stations near the South Texas coast and from one station near the wellhead (Table 1). Generally mousse particles occurred within or very close to areas covered with sheen, at an estimated concentration, based on scale-referenced sea-surface photographs, of 0.2–2.0 g mousse per m² of sea surface. Divers estimated that 99% of the mousse occurred on the sea surface. Flakes and pancakes did not always occur in the same sheen area. Flakes were collected with a stainless-steel screen and pancakes with a dip net. Station 1 was in a flake-pancake area of at least 20 km width, with flake concentrations ranging from 92 to 158 flakes m⁻² (470–806 mg flake m⁻²). This is ~400 times above the normal background tar concentration in that area of the Gulf⁶. Both types of mousse usually occurred in the shape of flattened disks with thickness usually less than one-fifth of the width. Samples were stored in filtered seawater in the dark at 4 °C in the presence of 0.02% sodium azide⁷. The visible production of thin sheen from mousse was not observed although at one point between stations, in the middle of a hot calm day, sheen was seen to be emanating from pancakes. Large numbers of flakes or pancakes in small volumes of water showed no tendency to aggregate. There was no size continuum between pancakes and flakes; the 1–4 mm thick flakes seemed to originate from the cracked scaly crust of the pancakes (Fig. 1a) and flakes could be produced by shaking pancakes in seawater.

Microscopic views of flakes are shown in Fig. 1b–h. Figure 1b shows the penetration of light through the edges of two flakes

observed with normal transmission light microscopy. Figure 1c, d shows the surface topography of two flakes viewed by reflected epifluorescence microscopy. Figure 1c shows the cracked surface of a flake that was touched by a Pasteur pipette. The light-coloured skin is shown on edge (S) and averaged 5–10 µm in thickness. The dark material within the cracks is emulsion (see also Fig. 1g). Figure 1d shows another flake with a more heterogeneous surface. The colour of the thin skin on an individual flake ranged from light yellow to brown. Often emulsion such as that in the upper-right corner of Fig. 1d was speckled with amorphous white fluorescent particles. Figure 1e shows a freeze-etched electron micrograph of the surface of flake skin with embedded diatom tests (D) and hundreds of flattened half-moon-shaped disks. Figure 1f is a blowup of the unidentified disks that are embedded flat and on end in the skin surface. Compared with flakes from Stations 2 and 3 flakes from Station 1 were highly contaminated with embedded material. Exposed emulsion on the surface of a flake is shown in Fig. 1g. Microbial colonies (M) were uncommon and usually occurred in isolated pockets on the flake. Loosely attached microbial cells and slime, such as on the edge of the flake in Fig. 1c, may have been more common but lost during sample transport. Microbial colonies were not observed on the brittle skin. Figure 1h shows a freeze-etched view of the interior of a flake that shows a smooth textured crude oil⁸ with a heterogeneous population of emulsified water droplets. The interior of flakes contained embedded particles such as dinoflagellate and diatom tests, fish scales and unidentified amorphous material. The pancake surfaces showed the same microscopic features as the flakes.

The pancake mousse exhibited gross chemical similarity to the wellhead mousse (Table 1), although their compositions were quite different: the latter containing significant quantities of saturated hydrocarbons in the *n*-C₁₀ to *n*-C₁₅ region (Fig. 2a) and large amounts of light aromatics (Fig. 2b), whereas the pancake mousse was almost totally depleted in alkanes eluting before *n*-C₁₅ and weathered such that only small levels of two ringed aromatics remained (Fig. 2c, d).

Mousse pancakes and their associated flakes were also compositionally different, (Table 1): the flakes were depleted in saturated hydrocarbons (*f*₁) and enriched in polar (*f*₃) content relative to the pancakes. Flakes were also more dense than their companion pancakes (Table 1) which could reflect a greater volume concentration of surface-embedded material than with the pancakes. Gas chromatograms of the mousse pancakes and flakes (Fig. 2c–e) indicate subtle but significant compositional differences between the two Ixtoc oil forms. The saturated (aliphatic) fraction of the flakes is more depleted in the lower boiling *n*-alkanes and reveals an unresolved complex mixture (UCM). Quantities of residual aromatics (Fig. 2d, f), consisting mainly of alkylated phenanthrenes and dibenzothiophenes, were reduced in the flakes although compositionally the two forms were similar. Figure 3 summarizes the hydrocarbon composition of wellhead mousse, Texas mousse pancakes and Texas mousse flakes. The presence of alkylated naphthalenes in the pancakes and their absence in the flakes indicates differences in the levels of the more soluble and potentially toxic naphthalenes in the mousse.

Changes in mousse composition can be attributed to rapid evaporation and dissolution⁹ in the early weathering stages and to photooxidation and evaporation in the later stages¹⁰. Differences between flake and skin compositions, reflected in severe depletion of aromatic hydrocarbons in the latter (compare Fig. 2f with h) are probably attributable to the importance of photooxidation in the skin. The high density of skin (>1.022 g cm⁻³) (Table 1) was due to a high proportion of embedded material.

The world oceans are widely polluted with floating petroleum residues—pelagic tar^{11–15}. Approximately one-third of the pelagic tar samples from the Gulf of Mexico¹⁶ and more than half of those from the central North Atlantic¹⁷ exhibit biomodal paraffin distributions in their gas chromatograms which indicate that the residues come from tanker sludge¹⁸. The remaining

† Pancake skin corresponds to the 5–10 µm skin shown in Fig. 1c, d. It was isolated from pancakes by shaking them in seawater. Flakes produced floated with the pancakes while the tiny pieces of skin sank to the bottom, indicating a density greater than seawater (>1.022).

‡ Oil collected at the wellhead with a GO-Flo bottle before it had reached the surface ('reference' wellhead mousse).

§ Density was measured by placing samples in solutions of different salinities. All samples sank at salinities 15‰ (1.009 g cm⁻³).

|| Fractions were isolated by silica gel column chromatography²⁷: Aliphatics-hexane eluate; aromatics-hexane/methylene chloride (50:50) eluate; polars-methanol eluate.

pelagic tar has a single paraffinic maximum in its gas chromatogram which is thought to be typical of weathered crude oils^{16,17}. The distinction between this type of pelagic tar and Ixtoc 1 mousse which also exhibits a single paraffinic maxima (Fig. 2c) is not clear. The presence of a stable water-in-oil emulsion seems to characterize mousse. Mousse pancakes and flakes from Stations 1 and 2 averaged 45–53% water as determined by centri-

fugation (after heating the mousse in a boiling water bath for 10 min). Water contents of pelagic tars have rarely been measured but presumably the waxy tanker precipitates contain little if any water, and the other so-called weathered crudes with single paraffin maxima may have been emulsion or mousse. It is not known whether mousse can become non-emulsified pelagic tar nor how crude oil composition effects emulsion formation

Fig. 2 Glass capillary gas chromatograms of f_1 , saturated (left column) and f_2 aromatic (right column) hydrocarbons from different Ixtoc 1 mousse fractions. An unresolved complex mixture (UCM) appears as a hump below the peaks in most of the chromatograms. *a, b*, Fractions from 'reference' wellhead oil obtained 0.4 km from the blowout (n -C₁₀, n -C₁₁, and so on represent n -alkanes; farn, farnesane; pris, pristane; phy, phytane; N, naphthalene; P, phenanthrene; DBT, dibenzothiophene C₁N, C₂N, C₁P, C₂P, C₁DBT and so on represent alkyl-substituted aromatics; GC, Hewlett Packard 5840A, 30-m SE-20 fused silica (J & W Scientific) splitless injection; temperature, 40–275 °C at 3° min⁻¹. Helium carries gas 1 cm³ min⁻¹ (*c, d*). Gas chromatograms of mousse pancakes obtained at Station 2 along the Texas coast ~875 km from the blowout site (see Table 1). and stability; some crude oils may even be incapable of forming pelagic tars because of low asphaltene content¹⁶.

Our microscopic examinations suggest that biological factors are not directly involved in causing Ixtoc 1 mousse to crack and flake. Extensive microbial colonization could have been inhibited by the rate of flaking, by photochemical oxidation products^{19,20} or by the lack of nutrient²¹ in the surface waters of the Gulf. Evaporative weathering and physical fragmentation are thought to be the principal processes affecting pelagic tar residues at sea²²⁻²⁴ and wave motion has been postulated as a mechanism for mousse fragmentation^{25,26}. Our observations suggest that weathering processes first form a cracked, scaly surface on pancakes which then 'flake' in turbulent sea. The flaking process exposes fresh mousse within the pancakes and this relatively unweathered mousse creates surface sheen which emanates from the pancake until a skin forms. The skin flakes off on agitation thus ultimately breaking down the mousse pancake as well as altering its composition.

Flaking of stable, water-in-oil emulsion particles seems to be a significant intermediate in the open-sea dispersion of the Ixtoc 1 oil spill. The process causes an increase in the surface-to-volume ratio of spilled oil which would accelerate surface-dependent evaporative dissolution and photochemical weathering and enhance the rate of microbial colonization. The increased density of the flakes relative to pancakes means that their lifetime in the water column may be shortened. The persistence of floating pancakes may be short-lived because of flaking.

We thank John Robinson, John Farrington, Donald Atwood, Pat Parker, Tony Amos and the scientists and crews of the RV Longhorn and RV Researcher for encouragement, constructive criticism and support. This work was supported by NOAA and a small grant from the Georgia Research Foundation.

Annual laminations in the sediments of Loe Pool, Cornwall

H. L. K. Simola

Karelian Institute, University of Joensuu, SF-80101 Joensuu 10, Finland

Annually laminated freshwater lacustrine sediments have been recorded at several sites in central Europe¹⁻⁵, North America⁶⁻¹³ and Fennoscandia¹⁴⁻²⁴. The presence of laminations may reflect either (1) regular changes within the lake ecosystem itself or (2) variation in the intensity of erosion and transport of material from the catchment, particularly where instability in the lake-watershed system has occurred as a result of human activities²². The principal cause of lamination is, therefore, seasonal variation of environmental conditions, particularly climate. Lakes with laminated sediments tend to be physically deep, exhibit a strong seasonal stratification, and be situated in areas of continental climate. We describe here what we believe to be the first reported instance of a long sequence of laminated lake sediments from Great Britain. Unlike most of the previous examples, these have been formed in a shallow, polymictic lake, in an oceanic climate.

Loe Pool (Fig. 1) is a eutrophic freshwater lagoon at ~4 m OD, 1 km south of Helston in south-west England (GR SW 648250, lat 50°4' N, long 5°17' W) with an area of ~44 hectares and a mean depth of 4 m. Its catchment covers ~50 km², and is mainly farmland, with one major settlement (Helston, population ~10,000). The main stream entering the pool is the River Cober, which drains ~90% of the total catchment. In the nineteenth and early twentieth century this area was the site of extensive mining operations, principally for tin²⁵.

Fig. 1 Loe Pool, Helston, Cornwall, showing depth contours (dashed line) and position of coring site (●).

Three sediment cores were taken from beneath ~7 m of water at the location shown in Fig. 1, where studies (M.A.C. unpublished data) indicate that an undisturbed conformable sequence of sediments is available. One was obtained using a 3-m version of the Mackereth corer²⁶ and two with 1-m *in situ* freezing device²⁷. The Mackereth core was frozen at ~-20 °C to preserve lamination. The surfaces of all cores were then cleaned while still frozen to facilitate description and photography of sediment structures. The stratigraphy of the three cores was easily matched by using prominent marker horizons and characteristic sequences of laminations.

The cores were then allowed to dry in the freezer for a few days to allow adhesive tape preparations to be made¹⁸. These enable the fine structure of the sediment to be examined,

especially for changes in abundance of sub-fossil diatoms. The stratigraphy of the sediment at the sampling site was:

0–40 cm: Highly organic *gyttja*, with four or five pairs of light and dark brown laminations just below the sediment surface (0–5 cm), the rest more homogeneous.

40–120 cm: Irregularly laminated sequence containing red and grey clays alternating with darker layers.

120–300 cm: More regularly laminated sediment consisting of paired grey and black layers, average thickness 3 cm per pair.

The sections 0–7.2 cm, 40–110 cm, 194–206 cm and 230–242 cm were examined. Remains of diatoms, other algae and vivianite crystals were recorded in consecutive 200-μm fields. We shall concentrate here on information obtained from the first and third sections, results being presented in Figs 2 and 3.

In all sections studied, diatom and other algal taxa appear in repeating sequences, the cyclic nature of which we attribute to seasonal algal production and sedimentation. It is therefore possible to define annual increments of deposition, which correspond closely with clearly visible stratigraphic changes. We can therefore identify laminations in these sediments which are truly annual in their nature. Interruptions to the sequence are mainly associated with the deposition of layers of clay, sometimes massive, in which diatoms are relatively scarce, and which we consider to represent dilution of diatom influx by allochthonous, clastic material.

For example, in Fig. 2 (0–7.2 cm), six phases (a–f) are defined. In each of these, *Thalassiosira pseudonana* and *Cyclotella meneghiniana* are succeeded by *Asterionella formosa*, *Melosira granulata* var. *angustissima* and then *Melosira varians*. In monthly plankton sampling of the pool by one of us (M.A.C.) in 1979, the first two taxa were prominent during spring and early summer, and the *Melosira* species in the autumn and winter. It is therefore considered that this sedimentary sequence records seasonal diatom succession in the pool, the *Thalassiosira*/*Cyclotella* stages representing the spring and summer, the *Asterionella*/*Melosira* stages the autumn and winter. The appearance of *Fragilaria* spp. and 'other' (mainly sessile) diatoms in layers thought to represent the winter, would then be consistent with the idea of increased influx of sediment from the littoral and the catchment during these months. Similarly, the summer abundance of *Pediastrum boryanum* in lake plankton samples is recorded in summer laminations. Crystals of vivianite ($\text{Fe}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$) seem to be concentrated in some winter layers. This has also been observed in Lovöjärvi (Finland)^{17,18}.

In this section, summer layers coincide with the lighter bands of sediment, and winter layers with the darker. Below 5 cm, however, the sediment structure and the diatom peaks are less

Fig. 2 IR photograph of and results of diatom, other algal and vivianite crystal counts from the section 0–7.2 cm of frozen sediment from Loe Pool.

Fig. 3 IR photography, and results of diatom and *Cysta microcarpa* counts from the section 194–206 cm of a frozen sediment core from Loe Pool. Irregular, diagonal striations are caused by ice-crystal formation during freezing of the Mackereth core.

well defined. Inspection of these and other cores indicates considerable bioturbation of the sediments between 5 and 40 cm.

Figure 3 (194–206 cm) shows a section in which five peaks of diatom deposition (*p–t*) are separated by relatively barren layers. The most abundant taxa present are *Chaetoceros muelleri*, *Surirella ovata* and *Synedra rumpens*, which tend to appear in a sequence which denotes seasonal succession. On three occasions, maxima of these planktonic diatoms are immediately followed by peaks of *Cysta microcarpa* (*sensu* Nygaard)²⁸. We interpret the planktonic diatom peaks, which coincide with darker bands of sediment, as representing the summer months, and the relatively barren layers, which correspond to the grey-brown clays, and in which 'other' diatoms largely occur, as the winter.

Figure 4 clearly shows that despite the oceanicity of the climate of this part of Europe, a pronounced winter maximum of rainfall and stream flow occurs, and that summer temperatures substantially exceed those of the winter. This contrast between the seasons seems sufficient to account for the formation of the Loe Pool laminations.

Fig. 4 *a*, Mean monthly streamflow (River Cober, 1970–79); *b*, mean monthly rainfall (1941–70); and *c*, mean monthly temperature (1960–74) for the Loe Pool catchment. Streamflow data from the South West Water Authority gauging station at Helston, rainfall data from Wendron, and temperature data from RNAS Culdrose.

From 300 to ~120 cm these consist of pairs of black (summer) and grey-brown (winter) layers, recording increased inflow of clastic material in the winter months, covering a period of ~60 yr. Then, between 120 and 40 cm, massive clay layers occur, which, according to diatom analysis not described in detail here (H.L.K.S. and M.A.C., in preparation), cover a period of only 7 yr. Here a high proportion of the sediment consists of material originating as mining wastes, and peaks in planktonic diatoms are separated by as much as 20 cm of clay in which diatom influx has been considerably diluted, thus indicating very rapid accumulation. We correlate this sequence with the most recent period of active mining in the catchment which ended in AD 1938. Within this section, two layers of red, haematite-rich clay occur, the upper at 40–46 cm, the lower at 65–70 cm. Documentation²⁹ shows that during the 1920s and 1930s the pool was heavily polluted by mining wastes, often to the extent that discoloration of the waters occurred. We therefore conclude that the red clay layers were deposited during this time. Between 1860 and 1920 active, but less intensive mining

Fig. 5 Scanning electron micrograph of *Thalassiosira pseudonana* Hasle et Heimdal from Loe Pool plankton samples. (Photograph Martin Coard.)

took place²⁵. Above 40 cm, laminations are not observed until ~5 cm from the sediment surface. Here there are four or five laminations which are not visually prominent, but which are well defined in the algal stratigraphy. Between 5 and 40 cm the sediment is considerably bioturbed, but ¹³⁷Cs analysis shows that the 1963 peak lies between 14 and 16 cm depth. This suggests a mean accumulation rate for the section between 16 cm and the sediment surface of 1 cm yr⁻¹, which is in agreement with the rate calculated from lamination counts just below the sediment surface.

The section 0–40 cm, between the top of the upper haematite clay and the sediment surface, thus represents the period since 1938, and has a mean accumulation rate very close to 1 cm yr⁻¹. Together with a sedimentation rate of 80 cm in 7 yr for the section 40–120 cm (based on diatom stratigraphy), and of 3 cm yr⁻¹ for the section 120–300 cm (based on lamination counts), this estimate allows us to conclude that the Loe Pool cores cover a period of ~110 yr.

Between ~1870 and ~1920 the main cause of lamination seems to have been a steady inflow of mining wastes in winter. During the period of most intensive mining (1920–38) this increased to massive proportions (80 cm in 7 yr). Between 1940 and 1975 laminations were not formed. The presence of the remains of numerous burrows indicates that this was a phase of considerable benthic activity. The formation of laminations in very recent years is attributed to increased eutrophy of the pool, which has led to occasional instances of anoxia at the sediment

surface during the summer months. These most recent laminations are therefore being produced in different conditions from those formed at an earlier date, which may in part account for colour difference between the respective summer and winter layers.

We thank Lieutenant Commander J. P. Rodgers and the National Trust for permission to carry out work at Loe Pool. We also thank R. S. Cambray for ^{137}Cs analysis and Dr A. C. Hamilton for the loan of a Mackereth corer. The work was carried out while H.L.K.S. and M.A.C. were supported by Devon Local Authority Research Assistantships, and H.L.K.S. by a grant from the Alfred Kordelin Foundation (Finland).

Supply of iron and manganese to an anoxic lake basin

W. Davison

Freshwater Biological Association, Windermere Laboratory, Ambleside, Cumbria LA22 0LP, UK

In seasonally anoxic lakes, the dynamic cycling of iron and manganese makes possible the study of geochemical cycling and processes of mineral formation, while the rapid lake processes may be a model for the analogous but slower oceanic processes. We have now measured concentration–depth profiles for iron and manganese to assess the flux of these elements from the sediments. The seasonal accumulation of iron in lake water can be accounted for by supply from the sediment, but the manganese profiles suggest that the major source of manganese is dissolution from particular material sedimenting through the water column.

This research is part of a concerted programme^{1,2} on the geochemical cycling of iron and manganese in lakes. The characteristic features of the process in lakes subject to deep-water anoxia are well known^{3–5}. Although the observed distribution of the various forms of iron in such conditions has recently been related to individual rate processes on the basis of detailed measurements¹, no such treatment exists for manganese. However, the concentration–depth profiles usually have a significantly different shape from those of iron, and this has been attributed³ to manganese being more easily reduced. It has been assumed^{3,6,7} that manganese is supplied from the sediment in anoxic conditions. Golterman⁸ speculated that

manganese oxides may be reduced in the water column to Mn(II) with concomitant oxidation of Fe(II), and Delfino and Lee⁹ realized that dissolution or desorption processes in the water column could be significant to the generation of Mn(II). Despite detailed studies of manganese in seasonally anoxic lakes^{9–11} the roles of dissolution of particulate matter or release from the sediment have not been clarified. However, most workers have looked at ‘macro-profiles’—concentrations measured at depth intervals of 1 m or greater—whereas to study sediment–water interactions ‘micro-profiles’—concentrations measured at centimetre distances from the sediment—need to be known.

Water samples were collected from the seasonally anoxic Esthwaite Water^{1,4,5} at approximately monthly intervals during the summer of 1980. A pump incorporating a sediment detector¹² was used to collect samples for both micro- and macro-profiles. The samples were analysed for Fe(II) and Mn(II) by polarography¹³, and for total iron and manganese by acid digestion procedures^{14,15}.

Figure 1 shows the results with respect to distance from the sediment and time of the year. Regression analysis of the micro-profiles for both total and soluble manganese measured between 5 and 50 cm from the sediment showed that the change in concentration with respect to distance from the sediment (dc/dz) did not significantly differ from zero ($P>0.8$). The mean of the 11 values for dc/dz was $-0.87 \mu\text{g l}^{-1} \text{cm}^{-1}$ (range -1.96 to $+0.52$). The slopes calculated from the macro-profiles, 0.5–1.5 m from the bottom showed that the total and polarographic measurements gave similar results and the value of dc/dz was $\sim -0.5 \mu\text{g l}^{-1} \text{cm}^{-1}$.

In contrast to manganese there is no polarographically measurable Fe(II) during May and June and it is only just measurable in early July (Fig. 1). During this time the total iron in the water column increases substantially. This has been explained^{1,4,5} by assuming that the oxidized sediment layer, which during the winter months overlies the very reducing sediment, is itself reduced when the lake stratifies and so Fe(II) diffuses into the water column. The overlying water is not then entirely reducing and so Fe(II) is oxidized almost immediately, and the resultant Fe(III) therefore builds up in the water column. When Fe(II) does appear in the water column in July and August a greater concentration gradient exists in the 25 cm of water nearest the sediment. Using regression analysis to calculate the slope reveals that the flux calculated from the micro-profiles was 10–30 times greater than that estimated from the slope of the macro-profile at 0.5–1.5 m.

Davison *et al.*¹ have shown that the lateral flux of iron supplied from sediment at the same depth as the water must be taken into account. Moreover, towards the latter part of the season, dissolution of particulate iron falling through the water column also becomes important. Thus the macro-profile cannot be used for estimating the direct flux from the sediment. However, from Fig. 1 it seems that in the confined zone of the bottom 25 cm of water the chemical gradient from the sediment dominates the lateral component of water movement and so a gradient which reflects the sediment–water interaction is established.

The seasonal increase in the iron and manganese in the bottom waters of the lake varies little from year to year^{1,4,5}. For 1979, 1.73 and 1.34 tonnes of iron and manganese respectively had accumulated in the larger lake basin by the end of the season. Assuming that both elements may dissolve for a period of 12 weeks from all that sediment which may possibly become anoxic, that is below 8.5 m depth, the mean micro-profile value for 23 July 1980 and 14 August 1980 of $-82 \mu\text{g l}^{-1} \text{cm}^{-1}$ for iron, results in 2.20 tonnes supplied from the sediment. For manganese, however, a slope of $-1 \mu\text{g l}^{-1} \text{cm}^{-2}$ results in 0.027 tonnes, only 2% of the manganese found to have accumulated in the lake. Therefore although iron may be sediment derived, even if a previously measured manganese concentration gradient, which is 5 times the value used here, is considered¹², manganese is not. This is verified by the shape of the manganese profiles. The virtual invariance of concentration with respect to depth in the stratified bottom waters indicates a lack of any

Fig. 1 The concentration of polarographically measured iron (Δ), total digested iron ($\blacktriangle$), polarographically measured manganese ($\circ$) and total manganese ($\bullet$) versus distance from the sediment. The position of the oxycline below which oxygen is not measurable ($<0.3 \text{ mg l}^{-1}$) by an *in situ* probe¹⁶ is indicated. On 12 May 1980 oxygen was still present at 4.8 mg l^{-1} near the sediment.

active point source or sink. Yet the progressive increase in concentration with time indicates a uniform supply of manganese at all depths. Comparison with the iron profiles shows that the shape cannot be accounted for by supply from lateral sediments; no similar increase in the waters in close proximity to the sediment is evident. On the macro-scale, supply from lateral sediment could not produce such a uniform profile because the ratio of sediment area-to-volume at any given stratum increases with depth.

Profile shapes show that at most 50% of the flux of iron at any depth is due to dissolution of particulate material¹. The calculation¹⁷ uses the concentration gradient and a knowledge of the vertical eddy diffusion coefficient to estimate the flux between each horizontal stratum of water which was assumed to be uniformly mixed. The lateral sediment derived flux was taken into consideration and any flux imbalance was attributed to *in situ* dissolution processes. Using the profiles of 14 August 1980 and 10 September 1980 for manganese the calculation suggests that dissolution accounts for 80–90% of the manganese flux. Although the approximations involved mean the results are semi-quantitative, the trend offers a possible explanation for the shape of the manganese profile. Particulate manganese from the inflowing streams must always be falling through the water column and may act as a source of supply for soluble manganese at all depths. The estimated 1.3 tonnes of manganese which accumulates in the hypolimnion results in a large increase in concentration in these bottom waters, but its contribution to the total manganese in the lake basin is not so great because of the relatively large volume of water in the surface layers. Before stratification uniform manganese concentration profiles with $100 \mu\text{g l}^{-1}$ of Mn could be measured, suggesting that 0.4 tonnes of manganese were present in the lake before any accumulation began. Moreover, it was estimated by gauging that $6 \times 10^6 \text{ m}^3$ of water flowed into the lake during June, July and August of 1980. The scant measurements indicate that the concentrations in the inflows are two to three times higher than in the epilimnion and so this volume of water probably carried ~ 1.2 tonnes of manganese into the lake. Therefore sufficient manganese must

either have been present in the lake or supplied to it, to account for the seasonal hypolimnetic increase.

The rapid increase in both polarographic and total manganese below the oxycline (Fig. 1) shows that the rate of vertical mixing in the metalimnion is not sufficiently rapid to mask the oxidation of the reduced form. Although the profiles of particulate manganese can be deduced from the difference between the two components plotted in Fig. 1, no conclusions can be drawn because the fraction of the particulate concentration which dissolves at any depth will depend on the rate of supply of manganese to the lake, the rate of dissolution, the sinking rate and the gradient of redox intensity. Simple solubility calculations show that neither MnCO_3 nor MnS can control the profile shape^{18,19}.

The build up of manganese in the hypolimnion therefore cannot be simply attributable to dissolution from the sediment. The shapes of the iron and manganese profiles show that simple vertical transport processes cannot account for the near-vertical manganese profiles and *in situ* supply by dissolution of sedimenting particulate material accounts for the observations.

The present results agree well with those of related studies. Eaton²⁰ showed that a considerable flux of the manganese in a fjord resulted from the dissolution of manganese oxides in anoxic conditions. There is evidence from estuarine work^{21–23} for manganese redissolving in the upper estuary where low pH and Eh prevail. The manganese profile in the permanently anoxic Black Sea has been modelled on the supposition of *in situ* dissolution²⁴. The same explanation may apply to a comparable peaked profile reported for a lake²⁵; slight peaks have also been reported for other lakes^{3,26}.

The interpretation of the iron and manganese ratios in the sediments of Esthwaite Water¹¹ has been based on the supposition that a substantial manganese fraction is lost from the sediment during anoxia: these results may require fresh interpretation. Care must be taken in extrapolating the results from artificially enclosed sediment–water systems to lakes^{4,5,27,28} because the possible input of manganese from dissolution of sedimenting particles is excluded. Mortimer^{4,5} reported the

presence of soluble manganese 40 days after Fe(II) had appeared in his laboratory tank experiments, which contrasts with the natural system where soluble manganese appears first.

Interstitial water profiles in sediments have been commonly used to estimate fluxes to the water column²⁸. The rate of transport is usually $\sim 10^3$ times slower than in the hypolimnion studied here. As micro-profiles discriminating to <25 cm are necessary for the hypolimnetic waters, by analogy the resolution of interstitial water measurements needs to be to <0.25 mm because lateral processes such as interchange with labile mineral fractions can still occur. Therefore caution should be exercised in using interstitial water profiles to estimate fluxes through the sediment-water interface.

Methylmercury production in the marine water column

G. Topping & I. M. Davies

Department of Agriculture and Fisheries for Scotland, Marine Laboratory, Victoria Road, Aberdeen AB9 8DB, UK

Although the biosynthesis of methylmercury in sediments is well established¹, this is not necessarily the exclusive natural source of methylmercury entering the marine food chain, particularly commercial fish and shellfish species for human consumption. An examination of mercury levels in freshwater fish², collected from a lake with a history of industrial mercury contamination, suggested that levels in fish are controlled in part by mercury in suspension and it followed that methylation should occur in the water column. Although methylmercury is present in seawater in coastal areas receiving discharges of waste containing either inorganic mercury³ or methylmercury⁴ there is no evidence that methylmercury is actually formed in the water column. We now present data which demonstrate that inorganic mercury can be methylated in the water column and we compare this production with that known to occur in marine sediments.

In May 1979 experiments to investigate the movement of inorganic mercury between the water column and sediments were carried out using a large plastic bag (3 m diameter $\times$ 20 m deep) moored in an arm of a sea loch (Loch Ewe) on the west

coast of Scotland. This type of enclosure, which is closed at the bottom, has been used⁵ to study the effects of low levels ($\sim 1 \mu\text{g dm}^{-3}$) of pollutants, particularly metals, on natural populations of phytoplankton, zooplankton and other trophic levels captured in the bags.

In our study, the seawater in the enclosure was initially spiked with inorganic mercury as HgCl_2 , to a concentration of $\sim 0.5 \mu\text{g dm}^{-3}$ using a method described elsewhere⁶. Seawater samples were analysed for total and 'reactive' mercury⁷. Sub-samples of the total settlement material, which was pumped daily from the bottom of the bag, were analysed for total mercury⁸, methylmercury⁹ and carbon (using a CHN analyser). Moderately active primary production was maintained by regular additions of nutrients to the plastic enclosure giving a

Fig. 1 a, Relationship between methylmercury and total mercury in settlement material. (Regression analysis: $y = 0.00885x$; $r = 0.91$ and standard error of slope = 0.00126.) b, Relationship between methylmercury and carbon in settlement material. (Regression analysis: $y = 1.233x$; $r = 0.85$ and standard error of slope = 0.294.) Both correlations are significant at the 0.01% level.

mean chlorophyll level of 10.9 mg m^{-3} and a mean fallout of organic carbon of $0.4 \text{ g C m}^{-2} \text{ day}^{-1}$.

Significant quantities of methylmercury ($1\text{--}10 \mu\text{g day}^{-1}$) were found in the settlement material. These concentrations were strongly correlated with concentrations of organic carbon ($r = 0.85$) and total mercury ($r = 0.91$) in settlement material; both correlations are significant at the 0.01% level (Fig. 1). Because the seawater in the bag was isolated from the natural sediments in the sea loch throughout the experiment and because the settlement material was not allowed to accumulate for a long

period (about 24 h), we believe that a large part of the methylmercury was formed within the water column.

The amount of methylmercury formed in suspension and collected with the settlement material is directly related to the total mercury associated with the particulate organic matter which in turn is dependant on the level of primary production. From Fig. 1 the ratio methylmercury (μg)/carbon (g) is 1.23 and the ratio methylmercury (μg)/total mercury (μg) is 0.0088; the latter may be compared with 0.001–0.003 estimated by Davies *et al.*³ for a contaminated estuary.

The present experimental results can be used to obtain a rough estimate of the importance of the formation of methylmercury in the water column. If the ratio of methylmercury to mercury of 0.0088 is a guide to what happens in the oceans, and assuming a mean concentration of mercury in the oceans¹⁰ of 10 ng dm^{-3} , the total quantity of methylmercury in open ocean water is 121,000 tonnes. From the global production of carbon¹, our measured ratio of methylmercury (μg) to carbon (g), and assuming that the rate of production of methylmercury is proportional to the total mercury concentration in open ocean, we estimate the amount of methylmercury formed each year in association with carbon fixation at 492 tonnes.

The estimation of methylmercury concentration and production in marine sediments is complicated by the wide range of estimates^{11–16} of methylmercury production rates, from 0.1 – $240 \mu\text{g cm}^{-2} \text{ yr}^{-1}$. Of the two estimates^{14,15} referring to sediments having low mercury concentrations, one¹⁵ includes both water column and sediment production and the other¹⁴ gives a minimum rate of production of $0.56 \mu\text{g cm}^{-2} \text{ yr}^{-1}$ based on uptake by plants and animals in the sediments (containing $2 \mu\text{g cm}^{-3}$ of total mercury). We use the latter value here. We take the mean concentration of mercury in marine sediments¹ as $0.3 \mu\text{g per g wet weight}$ ($0.45 \mu\text{g cm}^{-3}$) and the fraction of mercury present as methylmercury in sediments¹⁶ as 0.1%. If the relevant volume of the sediment compartment is $3.61 \times 10^{19} \text{ cm}^3$ (corresponding roughly to a 10-cm depth over a sea bottom surface of $361 \times 10^{12} \text{ m}^2$) the total methylmercury in marine sediments is 16,200 tonnes. Similarly, production of methylmercury by sediments amounts to 450 tonnes yr^{-1} .

Knauer and Martin¹⁷ found concentrations of 1.3–4.5 ng per g of methylmercury in selected phytoplankton samples from Monterey Bay, California. Using these data (mean value of 3 ng per g) and an annual primary production of $2 \times 10^{17} \text{ g wet weight}$ we estimate that the total amount of methylmercury associated with the annual global production of phytoplankton is ~600 tonnes. This value is comparable with one we obtained for phytoplankton using data from our bag investigations. By comparison, the quantity of methylmercury (~48 tonnes) associated with the annual global production of fish¹ is small.

These data indicate that not only is the 'standing stock' of methylmercury in the oceans greater than that in the surface sediments but that the annual production of methylmercury in these two compartments is similar. Investigations in the field are now necessary to verify our experimental findings and speculations.

Chondro-osseous morphology of *Dermochelys coriacea*, a marine reptile with mammalian skeletal features

Anders G. J. Rhodin*†, John A. Ogden* & Gerald J. Conlogue*

† Museum of Comparative Zoology, Harvard University, Cambridge, Massachusetts 02138, USA

The marine leatherback turtle, *Dermochelys coriacea* (Testudines, Dermochelyidae), is the largest known extant reptile, reaching weights >680 kg. It has a cosmopolitan oceanic distribution, nesting in tropical climates but migrating widely into colder temperate and boreal waters¹. Recent studies have shown that the leatherback has certain well developed thermoregulatory adaptations: vascular counter-current heat exchangers in the flippers, thick subcutaneous insulation beneath its leathery shell and effective inertial homoiothermy, if not endothermy^{2,3}. Whether this ability to maintain a body temperature higher than the ambient is due to endogenous endothermy or thermal inertia remains unclear^{4,5}. The skeleton of *Dermochelys* remains extensively cartilaginous even in adult animals^{6,7}, which has been attributed to neoteny secondary to its highly pelagic habitat, based on the assumption that its skeleton resembled that of typical embryonic turtles⁸. However, up to now there have been no studies of the internal architecture of the leatherback appendicular skeleton. We report here that the chondro-osseous morphology of *Dermochelys* is unlike that of any other known extant turtle or reptile but is more similar to that of marine mammals, notably Cetacea (whales) and Sirenia (manatees).

The typical hard-shelled marine turtles (Cheloniidae—genera *Chelonia*, *Caretta*, *Eretmochelys* and *Lepidochelys*) show a pattern of chondro-osseous morphology highly reminiscent of terrestrial or aquatic turtles^{9,10}. A thick, distinct compacta is clearly delineated from a medullary cancellous region and the epiphyses are covered by a very thin avascular cartilage which serves the purpose both of articular cartilage and physis, or growth plate. The subchondral plates of the epiphyseal bone surfaces are smooth and perfectly parallel to the articular cartilages. The only difference in marine turtles is the failure of development of a medullary cavity.

Dermochelys shows several important differences in skeletal morphology. In dried whole bones (with cartilage removed) the epiphyseal subchondral plates are not smooth, but instead present a rough, undulated, fenestrated surface which is not parallel to the contours of the articular cartilage surface (Fig. 1). In longitudinal sections of fixed whole bones each epiphyseal end has large cartilaginous epiphyses. Each of these, whether large or small, is filled with an extensive cartilage canal vascular system (Fig. 1). The vessels are both perichondral and transphyseal in origin and allow continuity of circulation between metaphysis and epiphysis. Both large and small vessels cross the physis: the smaller ones probably participate in endochondral chondro-osseous replacement, and the large ones are probably involved in cartilaginous expansion and nutrition of the epiphysis itself. No secondary calcification or ossification centres develop in any of these cartilaginous areas.

The diaphysis and metaphysis are filled with relatively dense cancellous trabecular bone without secondary medullary cavity formation. The metaphysis seems to be almost totally derived from endochondral bone formation and the diaphysis from a combination of endochondral and periosteal membranous growth. This is dramatically evident because of a combination of

Fig. 1 Dried whole humeri were prepared by dermestid beetle maceration from two *Dermochelys coriacea*, one *Eretmochelys imbricata* (hawksbill), three *Chelonia mydas* (green turtle), two *Caretta caretta* (loggerhead) and two *Lepidochelys kempii* (ridley). Sections of whole formalin-fixed humeri, radii, ulnas and metacarpals were examined from two *C. caretta*, two *L. kempii* and four *D. coriacea* (straight-line carapace lengths 135, 153, 175 and 178 cm, estimated weights 260, 360, 470 and 470 kg; specimens found stranded in New Jersey during August–October 1979, and obtained from the Marine Mammal Stranding Center, Atlantic City). *a*, *b*, Natural and dye-injected longitudinal sections of the proximal humerus in a *D. coriacea* of 135-cm carapace length: medial process apophysis on the left, proximal epiphysis on the right. Small vessels of perichondral origin are seen in the centre of the apophysis; large transphyseal vessels are seen in both the epiphysis and the apophysis. *c*, View end-on of dried proximal humeral epiphyseal subchondral plate (cartilage removed) in a *D. coriacea* of ~190-cm carapace length. Arrowhead points to small metaphyseal end-arterioles participating in endochondral osteogenesis; black arrow points to large transphyseal fenestrations allowing vascular access to the centre of the cartilaginous epiphysis. Also seen are coarse growth plate undulations, which probably serve as stabilization for the large chondroepiphysis.

dark pigmentation in the periosteally derived trabecular bone and lack of internal ontogenetic remodelling (Fig. 2). Cones of light-coloured endochondral and dark-coloured periosteal bone are therefore formed, which radiate in a well delineated manner from the central nutrient artery located at the anatomic site of the initial diaphyseal ossification centre (see radiograph, Fig. 2).

Transverse sections of the mid-humerus show a cyclical variation in bone deposition which is mainly peripheral, both in the endochondral and periosteal portions. Other than pigmentation differences it is difficult to delineate grossly endochondral and

periosteal bone and the impression gained is of an amedullary cancellous region merging gradually peripherally into a slightly denser compacta, which is extensively vascular in the deeper portions but less so superficially, where it becomes a very thin shell of dense subperiosteal bone.

In reconstructing the hypothetical growth of this bone, it seems that both patterns of bone formation occur contiguously for a certain period of time, with the endochondral cones of bone progressively diverging from each other at their bases and the intervening space being filled in by periosteal bone. However, in the sub-adult animal it seems that further elongation of the bone becomes solely derived from endochondral growth, with very little contribution from the periosteal bone apart from the continued formation of a very thin cortical compacta. This apparent change in growth pattern may represent a relative onset of skeletal maturity comparable with closure of the physis in mammals. However, as secondary epiphyseal ossification and growth-plate fusion do not occur in the leatherback, it is capable of continual growth throughout adulthood, this apparently being mainly endochondral.

In all these features of chondro-osseous morphology the leatherback turtle appears most similar to marine mammals, notably the Cetacea (whales)¹¹ and Sirenia (manatees)¹². Both of these groups also vascularize their epiphyses perichondrally and transphyseally, develop amedullary bones with retained endochondral and periosteal cones that are pigmented and do not remodel, show a gradual merging of cancellous into compact bone, and in some forms (the migratory beluga whale) also show cyclical bone deposition^{11,12}. The only discernible differences in the leatherback are the lack of secondary epiphyseal calcification and ossification, the point of relative cessation of periosteal growth in the sub-adult animal, and the presence of dark pigmentation in the periosteal rather than the endochondral bone, which is a reversal of the pattern seen in the marine mammals.

No other known extant reptile shows this combination of chondro-osseous developmental features. Whereas some extant reptiles (for example, the varanid lizards, including the large Komodo dragon) vascularize their chondroepiphyses, this vascularization is always perichondrally or circumphyseally derived, never transphyseally¹³. In addition, the vascularization is invariably followed by secondary calcification and ossification of the epiphysis. All other turtles and all crocodilians previously examined, including species of large body size, fail to vascularize their thin chondroepiphyses, which also remain cartilaginous throughout adulthood^{8,13}. However, certain extinct reptiles show some similarities to the leatherback: plesiosaurs have been described as having endochondral and periosteal cones that do not remodel¹⁴; ichthyosaurs, plesiosaurs, nothosaurs and mesosaurs are known to have amedullary bones with cancellous-compacta differentiation paralleling that of marine mammals^{15,16}, and protostegid turtles have also been noted briefly to be somewhat similar in this respect¹⁷. All these fossil reptiles were highly adapted to a marine existence as shown by other skeletal features. Some fossil amphibians with pronounced marine modifications (certain stegocephalian species) also show a pattern of bone histology very similar to that described for marine mammals¹⁸. Other extant vertebrates with marine adaptations have similar developmental patterns, notably pinnipeds (seals)¹⁹ and penguins²⁰. However, some marine vertebrates do not show this spectrum of characteristics—notably the typical hard-shelled marine turtles (Cheloniidae) which are, in most respects, similar to freshwater or terrestrial species.

No terrestrial vertebrate has these chondro-osseous developmental features. The fact that such diverse groups as cetaceans, sirenians, pinnipeds, penguins, extinct marine reptiles and amphibians, and leatherback turtles have such a high degree of physical similarity in bone morphology suggests an underlying mechanism of marine adaptability which has led to a highly developed pattern of skeletal evolutionary convergence. The failure of some marine vertebrates (for example, hard-shelled turtles) to develop these characteristics fully may

be related either to an incompletely evolved system due to relatively recent marine adaptation, or to a different set of physiological demands being required for differing life habits. Some studies have suggested that the marine pattern of bone development may be related to the homeostatic requirements of prolonged deep diving^{19,21,22}. It has been hypothesized that the intense dysbaric and acidotic challenges produced by repetitive deep diving can be countered by a skeletal buffering system which becomes more effective through increased vascularity in denser, amedullary bone¹⁹. Probably also of significance are the altered skeletal biomechanics of a marine existence where the limbs are not needed to support weight but instead are subject to entirely different forces produced by propulsion or steering in a medium much denser than air. Theories have also been advanced supporting hypothyroidism¹² and altered thermal relationships¹¹ as the underlying mechanisms leading to marine skeletal characteristics.

With regard to the phylogeny of *Dermochelys*, theories have vacillated between those supporting extreme specialization in a recently derived form and those favouring extreme primitiveness. Current taxonomic opinion accepts the former theory and is based on many similarities to the hard-shelled turtles²³⁻²⁸. However, strong arguments supporting the latter have also been advanced in the past^{7,8,29,30}. We suggest that the chondro-osseous morphology of *Dermochelys* emphasizes its extreme distinctness from other extant marine turtles (and turtles and reptiles in general). Whether this distinctness is recently derived or primitive cannot yet be answered.

Theories concerned with the phylogeny of endothermy and the origin of mammals from reptiles have stressed the relationships of increased body size and thermal inertia³¹ as well as altered bone histology³². It has been suggested that endothermy evolved separately in a number of extinct reptile groups³¹, and that transphyseal vascularization of a permanently cartilaginous epiphysis may have been the pattern in early mammal-like reptiles³³. The striking similarities in bone growth between *Dermochelys* and certain marine mammals, the presence of transphyseal vessels without secondary epiphyseal ossification, and the well developed homoiothermic (or endothermic) thermoregulatory adaptations suggest that this large animal may have developed along a course parallel to certain extinct endothermic reptiles, although in a group not previously thought to be undergoing this evolutionary process. In addition, the leatherback turtle's chondro-osseous morphology represents a striking and seemingly unique parallel between an extant reptile and modern marine mammals.

Genetic control for sibling recognition?

Andrew R. Blaustein & Richard K. O'Hara

Department of Zoology, Oregon State University, Corvallis, Oregon 97331, USA

The ability to distinguish between kin and non-kin is critical to current theories of altruistic behaviour and kin selection¹. Hamilton¹ predicted that individuals would behave differently towards one another depending on the genetic relatedness between them. When either proximity to or familiarity with kin is a good predictor of relatedness, the mechanism by which favouritism towards kin is accomplished may not require special kin recognition abilities^{2,3}. However, if proximity and familiarity are poor predictors of kinship, favouritism (hence increases in inclusive fitness⁴) could only be achieved by the differential

recognition of kin and non-kin. We have previously shown that *Cascades frog (Rana cascadae)* tadpoles reared with siblings prefer to associate with siblings over non-siblings⁵. The present study is the first to report that totally naive individuals (*R. cascadae* tadpoles) prefer to associate with siblings over non-siblings. Because tadpoles were separated before hatching and reared apart from other individuals, results suggest that the ability of these tadpoles to discriminate between siblings and non-siblings has some innate component.

Sibling recognition has been reported in experimental studies of spiny mice (*Acomys cahirinus*)^{6,7}, pigtail macaques (*Macaca nemestrina*)⁸ and American toad tadpoles (*Bufo americanus*)⁹. In each case, young were separated after birth or hatching and later given a choice of associating with siblings and non-siblings. In the mouse studies, sibling recognition was probably a result of learning during early development^{6,7}. Sibling recognition in pigtail macaques is possible in the absence of prior sibling association. It is unclear how sibling recognition develops in toad tadpoles. Although the existence of a genetic recognition system has been proposed in theoretical discussions of kin selection^{1,10,11}, experimental evidence (with the possible exception of the macaque study⁸) is lacking.

Two *R. cascadae* clutches were collected in the Oregon Cascade Mountains and transported to the laboratory in separate containers. Twenty eggs from one clutch (group A) were placed individually in opaque containers (A_1 individuals) at early embryonic development (yolk plug stage; stage 12, ref. 12). The remainder of the clutch (250 tadpoles) was reared in a single aquarium (group A). A second clutch was divided in half (groups B_1 and B_2 ; developmental stage 19, ref. 12) and each group was placed in a separate aquarium.

A rectangular tank (122 × 44 × 30 cm) was used to test two tadpoles simultaneously for sib group preferences. To create end compartments, a partition of 1.5-mm plastic mesh was placed 15 cm from each end of the tank. The remaining central portion of the tank was longitudinally divided by an opaque, water-tight partition. When testing A_1 individuals, 25 tadpoles from group A and 25 tadpoles from group B_1 were placed in opposite ends of the tank. When testing B_1 individuals, 25 tadpoles from groups A and B_2 were placed in opposite ends of the tank. For each test, these stimulus tadpoles were left undisturbed for 15 min. Then, at the tank centre, one tadpole was released on each side of the partition and allowed to acclimatize for 10 min. Each tadpole was tested in four 5-min trials at 10-min intervals. We recorded time spent in seconds in sib and non-sib halves of the tank.

Tadpoles reared in total isolation since early embryonic development (A_1) and tadpoles reared with sibs (B_1) but given a choice of unfamiliar sibs or non-sibs preferred to associate with sibs. Both the number of individuals spending most of their time on the sib side of the tank (18/20 for A_1 and 16/20 for B_1 ; $P = 0.001$ and $P = 0.006$ respectively, binomial test) and the number of seconds spent by each of these individuals were significant (Table 1). These results provide the first experimental evidence that an organism can recognize siblings after being separated from sibs while still embryos and after being raised in complete isolation.

Long-term field observations on the social and ecological conditions surrounding early development of *R. cascadae* indicate that ample opportunity exists for sibling groups to develop¹³. Females oviposit eggs in specific habitats in one or more localities around a lake or pond. Clutches are usually laid next to or on top of other conspecific egg masses. As they develop, dispersal from the site of oviposition tends to be low. Furthermore, larvae were never observed singly but always in close association with conspecifics. This tendency for *R. cascadae* to aggregate has been verified experimentally¹³. It is likely that natural groupings of this species are comprised of a high proportion of siblings and early development occurs in the presence of sibs and non-sibs.

Predation is probably one selective force for group formation in *R. cascadae* as they are palatable and preyed on by several

Table 1 Mean times out of 1,200 s spent by individuals on sib side of test tank when given a choice between sibs and non-sibs

Individuals tested	n	Seconds spent on sib side (mean ± s.e.m.)	T
A_1	20	702.6 ± 20.65	15*
B_1	20	682.2 ± 33.22	50†

Tests of A_1 tadpoles and B_1 tadpoles were made at 14–18 and 19–23 days post-hatching respectively. The Wilcoxon signed rank test (one-tailed; t represents the test statistic)¹⁸ was used to test for significant departures from an expected random distribution of total times on sib and non-sib ends. Individuals from group A_1 were reared in 0.5-l containers. The other members of groups A, B_1 and B_2 were reared in 38-l aquaria. All tadpoles were reared in the same room in a 14-h light 10-h dark photoperiod. The temperature in the laboratory was kept at 20–22 °C. Tadpoles were fed rabbit pellets *ad libitum*. The same 25 stimulus individuals were used for five tests, and were then discarded. Between tests, end compartment placements of As and Bs were alternated. Previously, two controls (20 tadpoles each from two different clutches) were run in the absence of stimulus groups to determine possible biases in the testing apparatus. In these controls tadpoles displayed a random distribution pattern⁵. Following each test, tadpoles were removed, the tank drained, rinsed and refilled to a depth of 6 cm with 34 l of dechlorinated tap water. No tadpole was tested more than once. Average developmental stages¹² for groups A_1 , A and B were 28.5, 28.0 and 28.0 respectively.

* $P < 0.005$; † $P < 0.025$.

species^{13,14}. Individuals can increase their fitness by living in groups and detection of predators increases with increasing group size¹⁵. Although kinship alone is not a necessary prerequisite for the evolution of groups, an individual in a group consisting of many sibs who warns others of a predator may increase its inclusive as well as its individual fitness compared with an individual giving a similar warning in a group with fewer or no sibs^{16,17}.

Our data may be added to the few reports^{6–9} which suggest that some species preferentially associate with sibs over non-sibs. Significantly, there is a major similarity and a major difference between the present study and that of Wu *et al.*⁸ which greatly enhance the conclusions of both studies. The use of paternal half sibs by Wu *et al.*⁸ and our use of individuals reared in isolation from an early embryonic stage show that individuals can recognize sibs without prior sib association. However, the macaques used by Wu *et al.*⁸ were allowed to associate with non-sib conspecifics during development whereas tadpoles in our study were reared in total isolation and had no exposure to conspecifics during development. Furthermore, we suggest that the ability to recognize sibs in *R. cascadae* may exist in early embryonic life. The results of this and another study to be reported in detail elsewhere⁵ are consistent with a genetic recognition system. In the latter study, two different clutches were reared from an embryonic stage in an aquarium separated by plastic mesh. This allowed chemical and visual contact between tadpoles during development. When given a choice of unfamiliar sibs or unfamiliar non-sibs, these tadpoles associated with unfamiliar sibs. When given a choice between a group comprised of an equal mixture of sibs and non-sibs (tadpoles with which they were reared) and an unfamiliar sib group, tadpoles associated with unfamiliar sibs. Although it is possible that individually reared tadpoles could imprint on their own cues (or subtle maternal cues from the egg mass jelly), results of tadpoles reared with non-sibs⁵ argue against this.

In organisms that undergo early development in the presence of non-kin (such as *R. cascadae*) or in those that disperse before associating with kin, a kin recognition mechanism that functions independently of experience may be required to achieve recognition. Our experiments are consistent with such a mechanism.

Substrate-adhering lymphoid cells show impaired tumorigenicity and increased immunogenicity

Jacob Hochman*, Aviva Katz, Efrat Levy & Shmuel Eshel

Department of Zoology, The Hebrew University of Jerusalem, Jerusalem, Israel

Cell adhesiveness is fundamental to a variety of biological phenomena, including tumour development and metastasis^{1–4}. Recently, Bubenik *et al.*⁵ have reported that in various malignant fibroblastoid cell lines those cells which demonstrated less adhesiveness were more tumorigenic. The relationship between cell adhesiveness, transformation and metastasis has been studied extensively in cells (fibroblastoid) grown as monolayers attached to their substratum and to each other^{4,6–9}, but, to our knowledge, there has been no report describing this relationship in suspension-borne (lymphoid) cells that grow free of each other and their substratum. We report here that substrate-adhering variant cells, selected from the tumorigenic, suspension-growing S49 mouse lymphoma, have impaired tumorigenicity. Furthermore, the substrate-adhering cells also have increased immunogenicity, as their inoculation into mice protects the mice from subsequent challenges with parental, non-adherent tumorigenic S49 cells. These findings suggest a new approach for the selection of immunogenic cells from suspension-borne tumorigenic cell populations.

In our study, a subline of S49 mouse lymphoma cells¹⁰, descendants of clone 24.6.1 (ref. 11), was propagated in suspension culture and readapted to grow as a transplantable tumour in BALB/c mice¹². Selection for cells with increased tumorigenicity was carried out through serial passages as tumours in BALB/c mice. Tumour cells from the 25th passage, which formed tumours as early as 7–10 days post-inoculation, were transferred into culture medium (subline T-25). These cells retained the same tumorigenicity *in vivo* for at least 6 months after transfer into suspension culture. From T-25 cells we have selected without the use of mutagens a subline (designated T-25-Adh) able to adhere to the substrate bottom of tissue culture flasks (Table 1). This selection involved continuous enrichment of substrate-adhering cells by discarding the cells growing in suspension. While attached to their substrate, these cells continued to grow until a dense monolayer was formed.

Table 1 Comparison between parental T-25 cells and their adherent variant (T-25-Adh) subline

Cells	Substrate adhesiveness	Tumorigenicity*	Immunizing† ability against T-25 cells in syngeneic mice
T-25	–	+	–
T-25-Adh	+	–	+

Cells were propagated in culture in Dulbecco's modified Eagle's medium (Gibco), supplemented with 10% heat-inactivated horse serum, penicillin (50 U ml^{–1}) and streptomycin (50 µg ml^{–1}). Cells were maintained at 37 °C in a humidified atmosphere containing 5% CO₂. Adhering cells were detached from their substratum (bottom of tissue culture flask) by shaking. Cells were adjusted to 1 × 10⁶ cells ml^{–1} and 10-ml portions were added to 50-ml tissue culture flasks (Costar 3050, 25 cm²) and incubated at 37 °C. At various intervals thereafter, flasks were tilted, aliquots taken out and the number of cells remaining unattached scored. From this, the percentage of attached cells was calculated. Although none of the parental T-25 cells attached, essentially all T-25-Adh cells attached to the substrate within 45–60 min. Assays were carried out only on samples in which viability, according to the trypan blue exclusion test, was >95%.

* BALB/c males, 8–10 weeks old, were inoculated with 1 × 10⁷ cells intraperitoneally. Mice were checked daily, and the first day on which tumours could be recognized was recorded. T-25 cells (*n* = 16) developed tumours within 7–10 days and all the mice died within 13–15 days. T-25-Adh cells (*n* = 14) did not develop any tumours for at least 90 days.

† BALB/c males inoculated intraperitoneally 90 days earlier with 1 × 10⁷ T-25-Adh cells (*n* = 10) and control BALB/c males (*n* = 4) were both inoculated with tumorigenic T-25 cells (1 × 10⁷ cells per mouse, intraperitoneally). Control mice developed tumours and died within 15 days, whereas all the mice that had previously received T-25-Adh cells did not develop any visible tumours for at least 180 days.

When the substrate was fully covered by a monolayer, cells appeared in the liquid phase of the medium above. These cells then continued to divide normally as a suspension of single cells or small aggregates of a few cells. When the free-floating cells were transferred to a new culture flask, they attached to the substrate with the same kinetics as their parental adherent cells.

When T-25 and T-25-Adh cells were inoculated into BALB/c mice, only mice that had received the T-25 (non-adherent) cells developed tumours (100% within 10 days) and died within 13–15 days post-inoculation. On the other hand, mice that received the same inoculum of T-25-Adh (substrate-adhering) cells did not demonstrate any visible tumours for at least 90 days (Table 1). These findings demonstrate that the selection for substrate-adhering S49 cells significantly decreases their tumorigenicity in BALB/c mice.

We tested whether the decrease in tumorigenicity of the substrate-adhering cells involved an immune response component, by exposing BALB/c mice that had previously received T-25-Adh cells to a challenge with 10⁷ tumorigenic T-25 cells per mouse. BALB/c mice of the same age group that had not been previously subjected to T-25-Adh cells were controls (Table 1). T-25-Adh cells were able to confer on BALB/c mice immunity against a challenge of suspension-growing tumorigenic T-25 cells. Furthermore, in preliminary experiments, the immunizing ability against T-25 cells could be adoptively transferred to BALB/c mice via spleen cells from mice previously inoculated with adherent (T-25-Adh) cells.

Both the selection for substrate adhesiveness and immunization procedures have been repeated with another tumorigenic subline, T-40 (derived from the 40th passage *in vivo*), and its selected adherent variant, and a tumorigenic subline derived from descendants of a different clone (24.3.2) of S49 cells¹¹. Here again, the adherent variant cells demonstrated impaired tumorigenicity concomitantly with increased immunogenicity when compared with their suspension-growing parental cells.

* Present address: Laboratory of Molecular Biology, National Cancer Institute, NIH, Bethesda, Maryland 20205, USA.

This report demonstrates for the first time that the relation between increased cell adhesiveness and decreased tumorigenicity^{5,9,13} may be applied to malignant cells of the lymphoid category. Furthermore, the impaired tumorigenicity of substrate-adherent S49 cells is, at least in part, the result of an increase in their immunizing ability.

Xenogenization or heterogenization are general terms now used to describe all attempts to make tumour cells antigenically foreign to their host so that they may be used more effectively in immunotherapy and immunodiagnosis. Several approaches are used for the biological xenogenization of tumour cells¹⁴⁻²¹, a comprehensive summary of which was published recently²². Our findings in S49 cells suggest a new and somewhat different approach for the xenogenization of malignant lymphoid cells. Here, the isolation of immunogenic, non-tumorigenic cells is based on a simple selection for substrate adherence. The nature of the cell-surface change(s) that took place on transition from free-floating to substrate-adhering, non-tumorigenic, immunogenic S49 cells is being investigated. Furthermore, it is of both mechanistic and practical significance to find out whether the approach taken here is also applicable to other lymphoid tumour cell lines.

Fibroblast traction as a mechanism for collagen morphogenesis

Albert K. Harris, David Stopak & Patricia Wild

Department of Zoology, University of North Carolina, Wilson Hall 046-A, Chapel Hill, North Carolina 27514, USA

To make visible the traction forces exerted by individual cells, we have previously developed a method of culturing them on thin distortable sheets of silicone rubber¹. We have now used this method to compare the forces exerted by various differentiated cell types and have examined the effects of cellular traction on re-precipitated collagen matrices. We find that the strength of cellular traction differs greatly between cell types and this traction is paradoxically weakest in the most mobile and invasive cells (leukocytes and nerve growth cones). Untransformed fibroblasts exert forces very much larger than those actually needed for locomotion. This strong traction distorts collagen gels dramatically, creating patterns similar to tendons and organ capsules. We propose that this morphogenetic rearrangement of extracellular matrices is the primary function of fibroblast traction and explains its excessive strength.

As a tissue culture cell spreads on one of our silicone rubber substrata, the traction force with which the cell margin pulls itself forwards compresses an area of the rubber sheet beneath the cell (Fig. 1a). The thin rubber sheet becomes folded into wrinkles of two kinds: compression wrinkles directly beneath the cell, running transverse to the force, and tension wrinkles which radiate outwards from the cell margins in the direction of maximum stretching. Of the cells we have examined, the strongest traction was exerted by fibroblasts from embryonic chick heart, skeletal muscle and tendon, dermis and the choroid coat of the eye, and by BALB/3T3 mouse cells. Individual cells of these types produced numerous wrinkles beneath and around themselves (Fig. 1a, b). Glial cells from dorsal root ganglia and platelets from human blood also exerted very strong traction. In contrast, epithelial cells (from embryonic chick epidermis, pigmented retina and liver parenchyma) were considerably weaker. These could still distort the rubber sheet, but only when many

Fig. 1 Tissue culture cell spreading on thin layers of silicone rubber. The traction by which the cells spread and propel themselves is shown by the wrinkles formed in the rubber sheet. Silicone rubber substrata were made by flaming the surface of 30,000 cP silicone fluid (polydimethylsiloxane, Dow-Corning; see ref. 1 for details of method). *a*, An individual 3T3 cell which has compressed the rubber layer beneath its leading margin into numerous folds. We call this pattern of distortion compression wrinkles. Scale bar, 10 μ m. *b*, Group of dissociated chick heart fibroblasts produce a more complex pattern of substrate distortion, composed of compression wrinkles and tension wrinkles, which radiate from the cell margins and often run between cells. Scale bar, 100 μ m. *c*, Although numerous growth cones extend in a wide band from this explanted dorsal root ganglion, no wrinkles form beneath or adjacent to them. The wrinkles visible are tension wrinkles originating from the two peripheral glial cells. Scale bar, 100 μ m.

Fig. 2 Collagen substrata are distorted by cellular traction in a pattern similar to the wrinkling of silicone rubber. *a*, Dermal fibroblasts spreading over a thin film of dried collagen produce a pattern of substrate folding, equivalent to compression wrinkling. Collagen solution (Vitrogen 100, Collagen Corporation) was pipetted onto glass coverslips, dried with a stream of sterile air and washed with phosphate-buffered saline (PBS) to remove the acid. Trypsin-dissociated fibroblasts from 7-day chick embryo skin were then seeded onto the collagen films. *b*, Dermal fibroblasts grown in reconstituted collagen gels do not generate wrinkles, but do align the flexible collagen meshwork around themselves. Around the cell body collagen is packed perpendicular to the direction of cell locomotion, while beyond the cell margins, sprays of collagen are aligned parallel to the long axis of the cell. This is equivalent to the compression and stretching seen in Fig. 1*b*. Collagen gels were prepared by mixing collagen solution with 5 × Dulbecco's modified Eagle's medium, fetal calf serum, NaOH and PBS (5:2:1:0.7:1.3 by vol) at 4 °C. Bar, 50 μm.

cells pulled in concert. Weaker still were transformed cells of the lines L-929 and CHO as well as SV40 virus-transformed 3T3 cells. These cells could only deform the rubber visibly where it was already wrinkled or torn. The weakest traction was exerted by macrophages (from mouse peritoneum), polymorphonuclear leukocytes (from human blood) and nerve growth cones (from embryonic chick sensory ganglia). Their weakness was not just a reflection of smaller size. Even when dozens of nerve growth cones lay side by side, their cumulative tractional strength was still too weak to distort our weakest rubber substrata (Fig. 1*c*).

Hence the paradox is that the most mobile cell types exert the weakest traction while the contractile strength of fibroblasts is very much larger than that needed for cell locomotion. To estimate the factor by which fibroblast traction exceeds that needed for locomotion, we have analysed time lapse films in which one margin of a spreading fibroblast breaks loose from the

wrinkled substratum so that it is pulled rapidly sideways by the elastic relaxation of the rubber. Such elastic retractions often displace fibroblasts by distances of many tens or even hundreds of micrometres, distances which correspond to the area of rubber sheet they had compressed beneath themselves while spreading. During these retractions the cell bodies are pulled at speeds of up to 10 μm or more per second, which is much faster than the speed at which the margin of these cells advances during normal locomotion (0.5–1 μm min⁻¹). When we consider that the elastic pull of the rubber cannot be any stronger than the cellular traction which originally distorted it, it becomes clear that the cell's traction is sufficient to propel it 100–1,000 times faster than normal cell locomotion. Thus we conclude that fibroblast traction is at least two or three orders of magnitude stronger than that needed to propel cells of this size at their normal speeds.

Fig. 3 Comparison of distorting effects of fibroblast traction on silicone rubber sheets and collagen gels. *a*, Marginal outgrowth zone of an explanted 8-day chick ventricle after 48 h in culture on silicone rubber. Adjacent to the explant (bottom of the field) the rubber layer is compressed into a mass of circumferential folds. Beyond the explant the silicone film is stretched resulting in radial wrinkles which continue far beyond the margins of the explant. *b*, The pattern of distortion is equivalent when heart explants are grown in collagen gels and viewed with polarized light. Adjacent to the explant a bright birefringent ring is visible consisting of a capsule of compressed collagen wrapped circumferentially around the explant. Next there is a dark band lacking birefringence where collagen is being compacted and pulled towards the explant by the migrating cells within this area. Collagen fibres farther from the explant are stretched, resulting in a radial pattern of fibre orientation. Scale bars, 100 μm.

Fig. 4 Two centre effects form in collagen gels even when explants are separated by a distance spanning over 1.5 cm. Collagen fibres become aligned into long axially oriented tracts interconnecting two centres of traction. Heart explants from 8-day chick embryos after 96 h in culture. Scale bar, 1 mm.

Fibroblast traction ought to distort any sufficiently flexible material and we have studied its effects on collagen, the normal substratum of fibroblasts within the body². When aqueous solutions of collagen are air dried to form thin sheets, fibroblasts wrinkle these sheets just as they do rubber substrata (Fig. 2a). When the collagen is reprecipitated as a thick gel, wrinkles are no longer formed. Instead, fibroblast traction compresses and packs the collagen fibres together around and behind the cell bodies. Beyond the cellular extensions which exert this traction, the collagen fibres are stretched into alignment (Fig. 2b). Bell, Ivarsson and Merrill³ have previously described the contraction of collagen gels by fibroblasts. Our observations suggest that these distortions are caused by direct cellular traction—the combined motility and contractility of the cells exerting strong shear forces tangential to their surfaces. Note that this traction is distinct from simple contraction like that of a muscle. For example, the cells elongate instead of shorten as they compress and stretch the collagen around them.

When tissue fragments are explanted into collagen gels, the cumulative traction of many fibroblasts pulls the gel centripetally to form a dense capsule of compressed collagen fibres wrapped around the explant surface (Fig. 3). The region of gel far from the explant is stretched into radial alignment with a 90° rotation in fibre alignment occurring where the fibroblasts exert their traction. Between adjacent explants the pull of this traction aligns the collagen into straight bundles (Fig. 4) which can be more than 1 cm long! The development of these traction fields demonstrates that collagenous structures such as tendons, ligaments, organ capsules and dermal tessellations⁴⁻⁶ need not be laid down by direct secretion of collagen fibres into their eventual arrangement⁷. Instead, fibroblast traction can rearrange and re-pack collagen into these patterns, even beginning from a totally random meshwork.

These traction fields resemble Paul Weiss' centre effects, which lends support to his theories of nerve guidance⁸ but suggests that guidance should be towards foci of strong traction rather than high growth rate. Our findings also point to fibroblast traction as the cause for the apparent contraction of collagen networks around deep wounds, burns and surgically implanted prostheses⁹⁻¹¹.

We had assumed originally that substratum distortion was merely an incidental by-product of cell locomotion, useful for studying its mechanism. However, these results suggest that traction has evolved to serve morphogenetic functions going well beyond cell displacement.

Genetically restricted cell-mediated cytotoxicity in cattle immune to *Theileria parva*

Elsie M. Eugui & David L. Emery

International Laboratory for Research on Animal Diseases,
PO Box 30709, Nairobi, Kenya

The protozoan parasite *Theileria parva*, which is transmitted by the tick *Rhipicephalus appendiculatus*, produces an acute fatal infection in the lymphoid system of susceptible cattle¹. This disease is a serious constraint to livestock improvement and production in large areas of East Africa¹. The parasite invades host lymphocytes, inducing rapid proliferation followed by widespread lymphocytolysis². Cattle which recover from theileriosis (East Coast fever) spontaneously, or which are immunized by infection and treatment with tetracycline³, are resistant to reinfection with the same isolate of *T. parva* for at least 3 yr⁴. Immunity against infection with the parasite cannot be ascribed to the production of specific antibodies⁵, but can be transferred adoptively between twins with thoracic duct leukocytes from the immunized partner⁶. These observations suggest that protective immunity is associated with cell-mediated mechanisms. We have now examined the capacity of leukocytes from immune cattle to lyse parasitized lymphoblastoid and non-parasitized tumour cell lines either directly or after stimulation in an autologous mixed lymphocyte reaction (MLR). In contrast to the nonspecific lytic activity of leukocytes from immune cattle reported by Pearson *et al.*⁷, we describe the sequential appearance in the lymph and blood of immune cattle, of cytotoxic leukocytes with activity restricted to target cells carrying the autologous genotype. These observations suggest that a major component of protective immunity to *T. parva* is mediated by cytotoxic cells which lyse parasitized cells in a genetically restricted fashion. We have also found that during a primary infection with *T. parva* cytotoxicity was manifested against allogeneic parasitized cells and xenogeneic uninfected target cells, but not against autologous infected cells. The features of cell-mediated immunity to *T. parva* during primary infection and immunization are discussed more fully elsewhere⁸.

Studies of cell-mediated immunity in cattle and other outbred species have been hampered by the lack of syngeneic cell lines for monitoring the development of cytotoxic responses. In the case of *T. parva*, this limitation has been overcome by using the

Fig. 1 The efflux in central lymph of normal and infected lymphocytes following challenge of three immune calves with fresh sporozoites adsorbed on autologous PBL. Results are expressed as mean average total (—) and blast lymphocyte output per hour (---); mean average percentage blast cells (—▲—▲) and mean average percentage of lymphocytes infected with macrophages of *T. parva* (—▲—▲), as determined by direct immunofluorescence¹¹.

ability of sporozoites of the parasite to transform *in vitro* leukocytes from normal cattle into lymphoblastoid cell lines infected with macrophages of *T. parva*⁹. We examined the specificity of cytotoxic responses of cattle immunized with *T. parva* using autologous and allogeneic infected target cells derived from such *in vitro* transformations, as well as xenogeneic non-parasitized cells (YAC-1). The latter is a mouse tumour cell line susceptible to lysis by natural killer (NK) cells of murine origin¹⁰, and we have found that it is lysed by normal bovine peripheral blood leukocytes (PBL).

Freisian calves aged 6–8 months, serologically negative for *T. parva*, were immunized by subcutaneous inoculation with sporozoites of *T. parva* (Muguga) and a concurrent intramuscular inoculation with long-acting tetracycline (20 mg per kg., Pfizer)³. Such immune animals were challenged subcutaneously 4 weeks later with the same isolate of the parasite from stablate or as fresh sporozoites adsorbed on autologous PBL. At intervals after challenge, cytotoxic responses were monitored in PBL. After a further 6 weeks, three calves received a subcutaneous inoculum of 5×10^8 autologous infected cells, and two calves were inoculated with another dose of infective sporozoites. Again, cytotoxicity was evaluated in PBL at intervals after the second challenge.

Table 1 Specificity of the cytotoxic response in immune animals after challenge with 5×10^8 autologous *T. parva*-infected cells

PBL donor	Target cell, <i>Theileria</i> -infected	% Specific lysis* (days after challenge)	
255	Th-256	3	7
	Th-588	2.1	48.2
	Th-589	1.0	0
	Th-589	0	0
588†	Th-588	5.3	70.1
	Th-589	0	39.0
	Th-256	3.8	2.2
	Th-589	7.1	39.7
589†	Th-588	4.5	51.5
	Th-256	4.7	0
	Th-589	5.0	5.3
Normal‡	Th-588	5.2	4.3
	Th-589	2.3	0.5

* Ratio of effector to target cells was 100:1 in macroassays (Fig. 2 legend).

† Animals 588 and 589 are chimaeric twins.

‡ Results are average of two normal control animals tested the same day as the immune challenged animals.

When immune animals were challenged with sporozoites as stablate, macrophage-bearing cells were not detected in biopsies of the draining lymph nodes during the ensuing 3 weeks, nor in lymph efferent from these nodes. Lymph node cells (LNC) from the draining lymph nodes were unable to stimulate an autologous MLR using normal PBL cryopreserved before the primary infection, whereas they stimulated allogeneic

Fig. 2 Three calves were immunized as described and were inoculated subcutaneously 4 weeks later with a lethal dose of sporozoites of *T. parva* (Muguga) from stablate. At intervals after challenge, PBL were purified using Ficoll-paque¹¹ (Pharmacia) and were tested in standard 4-h microcytotoxicity⁷ and macrocytotoxicity assays¹⁶ against autologous and allogeneic parasitized cell lines as well as a xenogeneic tumour cell line (YAC-1). All cells were suspended in RPMI-1640 culture medium (Flow Labs) supplemented with 10% (v/v) heat-inactivated fetal bovine serum (FBS), 20 $\mu\text{g ml}^{-1}$ glutamine and 10 mM HEPES buffer. For the microcytotoxicity assay, 5×10^4 target cells (in 50 μl) which had been previously labelled with 200 μCi ⁵¹Cr (Radiochemical Centre) for 1 h at 37 °C, were added in duplicate to 200 μl of effector cells in flat-bottomed microtitre plates (Linbro 96-TC), at effector : target (E : T) ratios of 80 : 1, 40 : 1, 20 : 1 and 10 : 1. Plates were incubated for 4 h at 37 °C in a humidified atmosphere of 5% carbon dioxide in air. Macroassays were performed in triplicate in plastic tubes, where 4×10^4 target cells (labelled with 150 μCi ⁵¹Cr for 30 min at 37 °C) were added to effector cells at E : T ratios of 100 : 1 and 50 : 1 in a total volume of 1 ml. The tubes were incubated as above for 12 h. Appropriate controls were included in both assays to determine total and spontaneous release of isotope. After incubation, 100 μl of supernatant was carefully collected from the microassay and 500 μl from the macroassay and counted in a γ -scintillation spectrometer (Packard). Results are expressed as the percentage of specific lysis calculated from the formula:

$$\% \text{ specific lysis} = 100 \times \frac{\text{c.p.m. in test} - \text{c.p.m. in spontaneous release}}{\text{total release c.p.m.} - \text{c.p.m. in spontaneous release}}$$

In addition, unidirectional MLRs were established using responder PBL from immune calves and stimulator cells from autologous infected cell lines which had been treated with 25 $\mu\text{g ml}^{-1}$ mitomycin C (Sigma) for 30 min at 37 °C. 4×10^7 PBL were added to 8×10^6 stimulator cells in 16 ml of culture medium (as above) supplemented with 10^{-4} M 2-mercaptoethanol, 100 IU ml^{-1} penicillin and 100 $\mu\text{g ml}^{-1}$ streptomycin. Aliquots (2 ml) were dispensed into 24 well $\times$ 16 mm culture plates (Linbro) and incubated at 37 °C in a humidified atmosphere of 5% CO₂ in air. After 5 d, the viable cells were recovered, washed and used in the microcytotoxicity assay. The figure depicts results from macrocytotoxicity test (a●) (50:1) direct (b■) and MLR-generated (c●) microcytotoxicity assays (40:1) using PBL effector cells against autologous (—) and allogeneic infected target cells (—○—), and efferent lymphatic lymphocytes (ELL) as effector cells against autologous infected targets (—▲—▲).

Fig. 3 Cytotoxic response of PBL from two immune calves after a second challenge with stablilated infective sporozoites of *T. parva* which were inoculated subcutaneously 10 weeks after infection and treatment and 6 weeks after the first sporozoite challenge. Results are depicted direct (a) and MLR-generated (b) microassays (40:1) using as targets autologous (—) and allogeneic (---) infected cell lines.

MLRs (data not shown). This result contrasted with the substantial autologous MLRs initiated by LNC during the second week of a lethal primary infection¹¹. When the challenge consisted of freshly isolated sporozoites adsorbed on autologous PBL, a transient parasitosis (<0.5%) was observed in efferent lymph from the draining lymph node on day 9. In these calves, the proportion of blast cells increased sharply from 5 to 30% on days 8–9 after challenge (Fig. 1). Cells from lymph nodes in which parasites were detected induced MLRs in normal cryopreserved autologous PBL. These results indicated that LNC are able to stimulate MLRs only when blasts, presumably infected cells, are present. Moreover, in immune animals challenged with sporozoites in the form of stablilate, the infection did not progress to a stage where macroschizonts could be detected by immunofluorescence or where infected cells could stimulate an autologous MLR.

Both challenge protocols with infective sporozoites elicited the development of cytotoxicity against autologous infected cells (Fig. 2a, b). Lytic activity was first detected in PBL 10–12 days after challenge, was maximal around day 14 when 20–50% of specific lysis was observed, and declined thereafter. Unlike in primary infections, no cytotoxicity was demonstrable against allogeneic cells or xenogeneic target cells at any stage. In one animal, lymphocytes draining from the regional lymph node exhibited cytotoxic activity against autologous infected cells from days 9–14, after the parasitosis had disappeared and before the detection of lytic activity in PBL (Fig. 2a, b). Calves re-challenged with a second inoculum of sporozoites as stablilate also showed cytotoxic responses in PBL which were again restricted to autologous target cells (Fig. 3a). These appeared at day 7, earlier than after the initial sporozoite challenge.

Similarly, strong cytotoxicity against autologous infected cells was found in three immune calves 6–14 days after challenge with 5×10^8 autologous infected cells (Fig. 4a, b). This lytic activity, which ranged between 20 and 60%, declined during the third week after challenge; once again, no activity was detected against allogeneic infected cells or xenogeneic tumour target cells. Moreover, the cytotoxicity was not due to any unique sensitivity to lysis of the allogeneic and autologous cell lines used: in experiments using crossed combinations of effector and target cells simultaneously, cytotoxicity was consistently observed against autologous but not allogeneic infected target cells

(Table 1). After challenge with autologous parasitized cells, leukocytes from two immune twin calves killed infected cells of their respective partners as efficiently as autologous cells (Table 1).

In other experiments, MLRs were performed using PBL from immune animals as responders and mitomycin-treated autologous infected cells as stimulators. When PBL were taken 21 days after challenge of immune animals with sporozoites and cultured for 5 days, a relatively low peak of cytotoxicity (~20%) was observed (Fig. 2c). When PBL were taken from immune cattle 7–24 days after challenge with autologous infected cells or with a second dose of stablilate, and cultured for 5 days, stronger cytotoxicity was detected (30–80%) (Figs 3b, 4c). In both cases, lysis was confined to autologous infected targets.

The present observations provide evidence that a population of specific cytotoxic cells is developed in cattle which have recovered from a primary infection with *T. parva*. These cells have the capacity to lyse autologous or cotwin but not allogeneic parasitized cells. The absence from peripheral blood of cytotoxic cells, and of precursors from which cytotoxic cells can be generated in MLR, at intervals other than those defined in this study, probably indicates that such cells reside in the solid lymphoid organs between encounters with the parasite. Following successive challenge with *T. parva*, specific cytotoxic cells enter central lymph and blood with a latent period progressively declining to a minimum of 6–7 days. Our findings demonstrate that cytotoxicity is effected directly by leukocytes collected from blood and lymph, discounting the necessity for an initial MLR to detect lytic activity⁷.

The genetic restriction of the cytotoxic response against *T. parva* in immune animals reported here contrasts with the lysis of allogeneic target cells reported by Pearson *et al.*⁷. The reasons for the discrepancy are not clear, but may reside in the multiple inoculations of autologous infected cells that those investigators

Fig. 4 Cytotoxic response of PBL from three immune calves at intervals after challenge with 5×10^8 autologous infected cells which were inoculated subcutaneously 10 weeks after immunization and 6 weeks after challenge with stablilated *T. parva*. Results are depicted from direct macrocytotoxicity tests (a) (50:1), direct (b) and MLR-generated (c) microassays (40:1) using as targets autologous (—) and allogeneic infected cell lines (---).

used to obtain PBL which expressed cytotoxicity after an MLR. Repeated challenges of immune calves with parasitized autologous cells in our studies has only yielded cytotoxicity of autologous infected target cells. After challenge of each of 18 immune animals so far examined, killing of allogeneic targets has not been detected in direct assays against a range of parasitized allogeneic cell lines. Alternatively, the former workers used only a single immune animal and one allogeneic infected cell target, and it was not established that this particular combination was genetically unrelated; effector and target could have shared some of the relevant histocompatibility antigens.

The restriction of cytotoxicity by the cells of immune animals to autologous or chimaeric twin partner infected target cells is analogous to the restriction of T-lymphocyte-mediated cytotoxicity of murine virus-infected cells¹², or hapten-modified syngeneic targets¹³. This is the first time that such restriction has been observed for a protozoan parasite. By analogy, cytotoxic lymphocytes from immune cattle may recognize complexes of parasite-specific antigens and polymorphic host determinants (probably major histocompatibility antigens), on the surface of infected cells. Analysis of this interpretation will require more information about products of the major histocompatibility complex in cattle than is yet available. The kinetics of appearance and activity of specific cytotoxic cells suggest that these cells represent a major mechanism of recovery from infection. They are observed in animals that are being immunized by infection and treatment, and in immune animals challenged with sporozoites or macroschizont-infected cells. Recovered animals that are immune to the homologous isolate of the parasite are susceptible to some other isolates of *T. parva*¹⁴. If specific cytotoxicity is correlated with resistance, the effector cells would be expected to kill autologous cells infected with isolates of the parasite to which there is cross protection *in vivo*. Experiments are in progress to clarify this point, with the objective of developing a laboratory test to ascertain whether isolates or antigenic types of *T. parva* might be cross-protective *in vivo*, an important prerequisite for a vaccination programme.

One approach to immunoprophylaxis against *T. parva* envisages using infected cell lines. With respect to this approach, genetic restriction of the cellular response to *T. parva* implies that successful prophylaxis requires the parasite to become established in the lymphocytes of the host. The factors which govern the transfer of *T. parva* macroschizonts from allogeneic to host cells have not been elucidated. Although this exchange can occur, the process seems to be relatively inefficient, which may account for the large number (of the order of 10⁸) of allogeneic cells required to infect or immunize cattle. In contrast, infections can be initiated with as few as 100 autologous macroschizont-bearing cells¹⁵. Studies are in progress in this laboratory to characterize the antigenic heterogeneity of the various isolates of *T. parva* and to define the nature of the genetic restriction involved in the acceptability of parasitized allogeneic cells by the host for vaccination. Cellular immunity to parasites has previously been attributed to production by lymphocytes of factors that activate macrophages so that they limit the multiplication of parasites within them. We now describe a new mechanism: direct killing by lymphocytes of parasitized cells. This may well also apply in other intracellular parasite infections, along with the genetic restriction defined here.

We thank Dr G. Büscher for theilerial sporozoites, Messrs R. Nelson for *Theileria*-infected cell lines and Tom Tenywa for technical assistance, Pfizer Laboratories for the provision of Terramycin LA, Drs A. C. Allison, S. Black, W. I. Morrison and Max Murray for constructive discussions and support throughout these investigations, and Ms Leah Agina for typing the manuscript.

Normal levels of natural cytotoxic cells against solid tumours in NK-deficient beige mice

Osias Stutman & Michael J. Cuttito

Cellular Immunobiology Section, Memorial Sloan-Kettering Cancer Center, New York, New York 10021, USA

Natural cell-mediated cytotoxicity (NMC) capable of *in vitro* lysis of various lymphoid and non-lymphoid tumours has been described in mice and other species, including man¹. NMC has been proposed as a first level of defence against tumour growth *in vivo*, one which does not need the priming of the conventional immunological response¹. The effector cells of NMC seem to belong to a special category of lymphoid cells, being neither classical T or B cells nor macrophages¹⁻⁵; natural killer (NK) cells have been proposed as the prototype effector cell¹, although some heterogeneity among effector cells seems to exist, depending on the target cells used for testing⁴⁻¹⁰. Two main subgroups of NMC effector cells have been defined: NK cells directed against lymphoma targets^{2,3,6,7} and natural cytotoxic (NC) cells directed against solid non-lymphoid tumours^{4,5,8-10}. We describe here another distinction between the two systems: while NK activity is low in mice homozygous for the beige (*bg*) gene¹¹⁻¹³ NC activity in spleen cell preparations from these animals is comparable with that observed in the appropriate controls (*bg*/+ and +/+ littermates). The *bg* syndrome of mice affects lysosome, melanosome and enzymatic functions and is a homologue of the Chediak-Higashi syndrome of man¹⁴. Defective NK activity in blood lymphocytes has also been reported in patients with Chediak-Higashi syndrome¹⁵. We also show that several mouse strains which have low NK activity, have normal or high levels of NC functions, expanding our previous observation that NC and NK cells are under distinct genetic control^{4,16}.

Table 1 summarizes the similarities and differences between NK and NC effector cells. As postulated earlier, it seems that NK and NC cells belong to a related, though distinct, family of effector cells, detectable in normal mice, which are capable of *in vitro* lysis of tumour cells without prior stimulation^{4,5,8}.

Table 2 shows our measurements of NK and NC activity of spleen cells against YAC-1 lymphoma and Meth-A sarcoma targets respectively, using C57BL/6J *bg*¹/*bg*¹ (line 4) and various controls (lines 1-3). Clearly NC activity is comparable in all groups studied, including the homozygous *bg* animals, while NK activity was detectable but significantly lower in the homozygous *bg* mice, in accordance with published reports¹¹⁻¹³. A small group of SB/Le mice which carry the *bg* gene derived from a radiation-induced mutation (the *bg*¹ being a spontaneous mutation)^{17,18} was also studied (lines 5 and 6). While NC levels between the homozygous *bg* and controls were comparable, NK activity was again markedly reduced in the homozygous *bg* (line 6). F₁ hybrids between C57BL/6J *bg*¹/*bg*¹ and SB/Le *sa bg*/*sa bg* also showed the same low NK reactivity (line 8), supporting the view that both *bg* mutations are acting on the same gene^{17,18}, and that the NK defect is not associated with the satin (*sa*) gene¹⁷.

In addition, Table 2 (lines 9–13) shows that other mouse strains such as A/J and some sublines³, SJL/J (S. Kaminsky and G. Cudkovic, personal communication) and I/St mice, which show low levels of NK activity when tested against YAC-1 targets, have normal levels of NC function against Meth-A sarcoma targets ('normal' means comparable with the syngeneic BALB/c strain⁴). Furthermore, I/St mice belong to the group of mouse strains with the highest NC reactivity against Meth-A targets^{4,8}.

The observation that transplanted tumours grow better and produce more metastases in homozygous *bg* mice^{19–21} supports the view of a possible *in vivo* surveillance role^{2,3} of the NK cells. On the other hand, one study, using a small group of homozygous *bg* and controls (8 mice per group), also showed that the incidence and time of appearance of sarcomas after administration of 3-methylcholanthrene were comparable²¹. This suggests that such 'normal' tumour incidence after chemical carcinogenesis in *bg* mice may be due to the adequate levels of NC cells present in such animals, as described here. Much larger groups of animals, as well as different carcinogen dosages have to be tested in homozygous *bg* mice and controls before this issue is settled. A similar speculation was made concerning the 'normal' incidence of spontaneous and induced tumours in athymic nude mice²², which have high levels of both NK^{2,3} and NC^{4,16} activity. The single published study on incidence of spontaneous tumours in *bg* mice¹⁷ showed that while the homozygous SB/Le *bg* animals had increased susceptibility to pneumonia, the incidence of lymphomas or other tumours was not increased. In fact, the incidences of lymphoproliferative lesions and lymphomas seemed to correlate more with the recessive gene *sa* than with *bg*¹⁷. Some cases of Chediak-Higashi syndrome in man develop a lymphoma-like tumour²³.

Similar comments can be made concerning the other mouse strains with low NK but normal NC activity described in Table 2 (lines 9–13). With the exception of SJL mice, which develop a high incidence of a reticulum cell lymphoid neoplasm²⁴, none of the other strains can be catalogued as having high tumour incidence^{24–27}. A/J mice show high incidence of lung adenomas at 18 months of age^{24,25} and mammary tumours in breeding females^{24,25} which are comparable with other mouse strains with normal NK activity. I/St mice in addition, are quite resistant to polycyclic hydrocarbon carcinogenesis^{26,27}. Again, as speculated, the 'normal' incidence of the common mouse tumours²⁴ in these strains with low NK activity (and also in the case of A/J mice with a deficient ability to generate tumoricidal macrophages²⁸) may be due to the normal NC activity observed in these animals. The low NK activity in the SJL may contribute to the high incidence of lymphoid tumours in such animals. On the other hand, additional factors may also be operative in SJL mice, as these animals were specifically bred for high incidence of the lymphoid tumours²⁴, and the incidence of spontaneous lymphomas is not clearly increased in mouse strains with low NK activity such as A sublines and 129/J (see ref. 3 for NK information and refs 24 and 27 for lymphoma incidence). Anti-cancer surveillance theories (whatever the mechanism for such surveillance) have predicted that an increase in tumour incidence would be the consequence of any spontaneous or induced interference with the surveillance device²⁹, but this was never clearly fulfilled for any surveillance model in animals or man^{27,30}.

It is tempting to speculate that NK–NC cells represent some form of alternative pathway of immunological surveillance ('alternative' meaning that it is not mediated by T cells as originally proposed in the theory²⁹, but that it is serving the same purpose of handling incipient tumours). Thus, animal models showing selective deficits of NK activity may become important for the determination of the *in vivo* role of such cells. However, using the same type of argument that we used in our criticism of the T-cell dependency of immunological surveillance^{22,27,30}, it may be that the effects detected in the NK–NC systems against tumours are only by-products of effector systems which serve other functions *in vivo*, perhaps related either to regulation of

Table 1 Comparison between NK and NC effector cells of natural cell-mediated cytotoxicity

Similarities	Differences
Pre-existing high levels in normal hosts, no need for apparent priming	Mouse strain distribution of activity
No evidence of immunological memory	Age of appearance
Levels of activity influenced by interferon	Affect of <i>in vivo</i> treatment with ⁸⁹ Sr, oestrogen, cyclophosphamide
Type of activity (that is, activity against otherwise negative targets) influenced by interferon and interferon inducers	Surface determinants (FcR, Thy-1, NK 1, Qa 2 and 5, Asialo GM1)
No H-2 restriction for cytotoxicity	
High reactivity dominant in F ₁ hybrids	
Present in athymic nude mice	
Tissue distribution	
No surface Ig and Ia negative	
Non-adherent	
Non-phagocytic	
Size	
<i>In vivo</i> effects of irradiation and steroids	
Blocking of cytotoxicity by monosaccharides	

NC^{4,5,8–10} and NK³ cells were compared using mostly NK data with YAC-1 targets. Some of the properties suggesting differences are not general: NK cells against EL4 lymphoma targets are not affected by *in vivo* treatment with ⁸⁹Sr (ref. 6), as are NC cells⁸; age of appearance of NC activity is usually earlier than NK, although that is dependent on the target cells used and in some cases activity is detected only at 3–4 weeks of age, as with NK⁹; with surface determinants, although NC cells are negative for those listed above^{5,8}, note that while some markers like Asialo GM1 seem to be present on all NK effector cells³⁴, other markers such as Thy-1, FcR or Qa 5 may be present only on fractions or subpopulations of NK cells^{37,38}. The surface phenotype of most NK cells is NK 1 (refs 7, 38), Qa 2 (refs 38), Qa 5 (ref. 38) and Asialo GM1 (ref. 34) positive, while fractions of NK cells also express Thy-1 (refs 37, 38) and receptors for Fc (refs 2, 3). All these markers are absent from NC cells^{5,8,39}. Other markers present on NK cells not yet tested in NC include Ly 5, Ly 6 and receptors for *Helix pomatia*^{1–3,38}. Some of the similarities also deserve comment. For example, NC cells show a certain degree of adherence to nylon wool⁵ which was also observed with certain types of activated NK cells^{1–3}, although the bulk of NK activity is non-adherent to nylon. The blocking of NCMC by monosaccharides¹⁰ also shows differences: while NC cells show some selectivity to blocking by D-mannose (and galactose), NK cells show less selectivity and other physiological sugars can also block NCMC. For a review see ref. 39.

haematopoiesis, defence against virus or other infectious or parasitic agents^{1–3,8,14}.

Note three points concerning the present comparisons: (1) The NK defect observed in beige mice, although profound, is not total, and some degree of reactivity can be observed either in long-term assays (G. Cudkovic, personal communication) or after *in vivo* administration of interferon inducers^{19,31,32}. Thus, the present comparisons using a 4-h assay for NK but a 24-h assay for NC cells can be questioned. Kinetic studies of NC-mediated cytotoxicity have shown that most of the activity occurs within the first 12 h (refs 5, 8), there is no 'activation' of NC (or NK) cytotoxicity after 24 h in the assay and there is undetectable production of interferon during the 24-h assay (E. Lattime, W. Stewart III and O. S., unpublished results), suggesting that NC cells are not a special kind of *in vitro* activated NK cell. In addition, the differences in the expression of surface antigens between NC and NK cells also argues against such an interpretation, especially as activated NK cells also express such markers as Qa 5 and Asialo GM1 (refs 33, 34). (2) Although the beige mice seem to be defective solely in NK-mediated cytotoxicity^{11–13}, *in vitro* antitumour cytostasis and cytotoxicity by *in*

Table 2 NC and NK activity of spleen cells from C57BL/6J, homozygous *bg*^J, heterozygous *bg*^J and controls, and from other mouse strains with low NK activity (A/J and sublines, SJL/J and I/St)

All mice were 6–8 weeks old when used as spleen cell donors, and in most cases were simultaneously tested for NC and NK activity. The beige mice, controls and A/J mice were obtained from Jackson Laboratories; the SJL/J mice were a gift from Dr G. Cudkovic; the A and its congenic pair A/T1a^b were obtained from Dr E. A. Boyse; the I/St mice were from our colonies⁴, as were the *bg* F₁ hybrids and controls. All values presented are mean ± S.E.M. of individual mice. Numbers in parentheses indicate number of mice tested simultaneously for NK activity. For details on the BALB/c sarcoma Meth A and the A/Sn lymphoma YAC-1 see refs 4, 5, 8, 10. NC activity was tested using ³H-proline-labelled adherent target cells, 100, 50 and 10 effector/target ratios and 24-h incubation as described in refs 4, 5, 8. NK activity was tested with ⁵¹Cr-labelled YAC cells in suspension, using the same effector/target ratios in 4-h release assays as described in ref. 10.

* As only three animals were tested, the results are presented as mean and range in parentheses.

† One animal had 32, 21 and 20% cytotoxicity at the three effector/target ratios tested. All the others had values of 15% or less at the 100:1 ratios.

in vivo activated macrophages is defective³⁵, while activity of *in vitro* activated macrophages and promonocytes of *bg* mice may be normal^{11–13,35}. Thus, the beige mice may have additional defects of cells, such as macrophages, putatively involved in defence against tumours, making *bg* an interesting model of NCMC deficiency, but certainly not the litmus test for definition of NK function *in vivo*. (3) The apparent tumour 'selectivity' of the NC–NK system for solid tumours versus lymphomas deserves comment. One proposed terminology even uses NK_L for the conventional antilymphoma activity and NK_S or NK_{solid} for a cell with similar characteristics as NC, although tested in a different assay⁷. 'Solid' is used throughout, in the traditional pathologist's sense, opposing it to the diffuse malignancies such as leukaemia, and not defining a particular state of matter. Such tumour-type preference of NC and NK may not be absolute. Metastatic spread to the lungs of any type of tumour may be controlled by NK-like cells^{19,36}, while tumour growth in other sites may be controlled by NC-like mechanisms, at least for certain solid tumours. The *in vivo* studies with beige mice show a deficient response to lymphomas²⁰ and melanomas¹⁹ (technically a solid tumour, although 'modified' to be sensitive to NK cytotoxicity⁷ by long-term *in vitro* passage¹⁹). Such deficiency is evidenced by an increase in local growth of the lymphomas²⁰ and an increase in spontaneous and artificial lung metastasis from solid tumours^{19,21}. On the other hand, local tumour growth of melanoma¹⁹ or the Lewis lung carcinoma³⁵, as well as the appearance of lymph node melanoma metastases¹⁹ were comparable in beige mice and controls. It is also tempting to speculate that the differences between tumour type and NC or NK cytotoxicity are due to the predominance on certain tumours (lymphomas compared with solid tumours) of determinants that are recognized by NC and NK cells respectively, perhaps related to either concentration or appropriate display of certain monosaccharides associated with membrane glycoproteins or glycolipids, as may be suggested by our studies of blocking of cytotoxicity, showing D-mannose preference for the NC system¹⁰.

Thus the beige mutation which affects NK cells has no effect on NC activity, a situation observed in other low-NK mouse strains such as A/J and sublines, SJL/J and I/St. Whether this situation explains the overall low tumour incidence of most of these strains, if indeed NCMC is considered as an antitumour surveillance device, needs further study.

This research was supported by grants CA-08748, CA-15988 and CA-17818 from the NIH and grant IM-188 from the American Cancer Society. We thank Mary L. Devitt for the animal care, Linda Stevenson for preparation of the manuscript, Drs Edmund Lattime, Stuart Macphail and Richard Miller for criticism and Dr G. Cudkovic for providing unpublished results.

Idiotypic regulation by isologous monoclonal anti-idiotope antibodies

M. Reth, G. Kelsoe & K. Rajewsky

Institute for Genetics, University of Cologne, Weyertal 121, D-5000 Köln 41, FRG

The network hypothesis¹ proposes that internal antibody interactions are crucial in the regulation of the immune system. Thus, injection of minute amounts of anti-idiotypic antibodies (antibodies specific for a particular set of antigenic determinants (idiotopes) associated with the variable region of a particular antibody or set of antibodies) can enhance or suppress the production of the corresponding set of idiotopes (the idiotype) in subsequent antibody responses of the animal^{2–5}. We have recently shown that idiotope expression can be enhanced and suppressed by monoclonal anti-idiotope antibodies of the IgG1 class in concentrations approaching those of natural antibodies⁶. We now demonstrate that these regulatory effects are not due to differences in the constant parts of the injected antibody and antibodies of the IgG1 class in the recipient. Also, an IgG2a anti-idiotope antibody raised in C57BL/6 mice suppresses the expression of the corresponding idiotope in animals of the same strain when minute amounts are injected 2–8 weeks before the test immunization with antigen. These results indicate that antibody-mediated network interactions are physiologically important and suggest that the class of isologous anti-idiotypic antibodies may influence their regulatory properties. Finally, the enhancement and suppression of idiotope expression by IgG1 anti-idiotopes and the suppression by IgG2a is almost exclusively at the level of IgG but not IgM antibodies.

We developed previously, by the Köhler–Milstein cell hybridization technique⁷, a series of monoclonal antibodies of mouse origin each of which recognizes a particular idiotope characteristic for a subset of anti-NP (NP = 4-hydroxy-3-nitrophenyl-acetyl) antibodies of C57BL/6 mice⁸. When IgG1 antibodies of this type were injected into C57BL/6 mice and the animals immunized with an NP-carrier conjugate 1–8 weeks later, the expression of the corresponding idiotope in the anti-NP antibody population was either enhanced or suppressed, depending on the dose of anti-idiotypic antibody: nanogramme amounts led to enhancement, microgramme amounts to suppression (ref. 6 and unpublished observations).

The antibodies used in these experiments originated from CBA mice and thus differed in allotype from IgG1 antibodies of the C57BL/6 strain. The experiment was therefore repeated in (C57BL/6 × CBA)F₁ animals for which the anti-idiotope antibody would be 'self', at least with respect to its constant part. Groups of five animals were injected with 10 ng or 10 µg antibody Ac38 and immunized with NP₈-CG (CG = chicken γ-globulin) 4 or 6 weeks later. The experimental conditions were exactly as described in our previous paper⁶, except that the anti-idiotope antibodies were diluted in phosphate-buffered saline containing 5 µg mouse serum albumin per ml. The animals were bled 12 days after immunization with antigen and the sera were titrated for λ₁-bearing anti-NP antibodies and the

Ac38 idiotope (the idiotope recognized by antibody Ac38). This idiotope is expressed within the λ-bearing antibody population which represents a major portion of the total primary anti-NP response in mice expressing the *Igh^b* haplotype^{9,10}. The results of the experiment are depicted in Fig. 1.

It is clear that 10 ng of antibody Ac38 enhance and 10 µg of the antibody suppress the expression of the Ac38 idiotope in the primary anti-NP response. There is no effect on the total amount of λ₁-bearing anti-NP antibodies. These results are strictly analogous to those previously obtained in C57BL/6 mice⁶ and thus demonstrate that allotype disparity is not responsible for the regulatory effect of these anti-idiotope antibodies.

Sera from one of the two experiments depicted in Fig. 1 were analysed for the class distribution of idiotope-bearing and total anti-NP antibodies. The sera from the control groups were not available for analysis, as they had been used up in absorption experiments in which it was shown that elimination of NP-binding molecules from the sera also led to the elimination of more than 90% of idiotope-bearing molecules. We therefore included in the analysis sera from our previous experiments⁶, in which antibody Ac38 had been injected into C57BL/6 mice instead of (CBA × C57BL/6)F₁ animals. The results are shown in Fig. 2.

The sera from the F₁ experiment were titrated for IgM, IgG1, IgG2a and IgG2b (Fig. 2a). IgG2a anti-NP antibodies were not detectable and IgG1 was the predominant class. The level of antibodies bearing the Ac38 idiotope was high in IgG in the 10-ng group and reduced to background in the 10-µg group.

Fig. 1 Serum antibody levels from (CBA × C57BL/6)F₁ mice injected with: a, 10 µg Ac38 (△, ▲); b, diluent (□, ■); and c, 10 ng Ac38 (○, ●) 4 or 6 weeks before immunization with 100 µg NP₈-CG. Mice were bled 12 days after immunization and individual serum samples collected for analysis. Individual values from the results of a solid-phase radioimmunoassay are plotted as µg ml⁻¹ of λ₁-bearing antibody⁶. Open symbols represent the total amount of NP-specific antibody, closed symbols represent that fraction of antibody bearing the Ac38 idiotope.

In contrast, at the level of IgM, both groups exhibited similar levels of Ac38-positive anti-NP antibodies. The notion that the regulation of idiotype expression by antibody Ac38 operates mainly at the level of the IgG response is further supported by the data of the experiment with C57BL/6 mice (Fig. 2*b*). In this case the sera were analysed for idiotype expression in IgM and IgG1 as the major IgG component. Obviously enhancement of Ac38 expression appears mainly in IgG1 and not at all in IgM; suppression is complete in IgG1 and only partial in IgM.

One might still argue that the experiments documented in Figs 1 and 2 do not reflect a physiological process in the immune system because antibody Ac38 was not induced in the strain expressing the Ac38 idiotype (C57BL/6), although this argument does not seem to make much sense in view of the extreme diversity of the antibody system. Nevertheless, we have started to produce, in the same idiotypic system, monoclonal anti-idiotype antibodies of C57BL/6 origin. For this purpose C57BL/6 mice were sensitized with a conjugate of keyhole limpet haemocyanin and the anti-NP antibody B1-8, a monoclonal IgM of C57BL/6 origin—the same protein against which our previous anti-idiotype antibodies had been raised⁸. The animals were boosted with the same conjugate 2 weeks later and their spleen cells fused with the myeloma line X63.Ag8-6.5.3 (ref. 11) 3 days after boosting. All technical details of immunizations, the cell fusion technique⁷, the detection, cloning and propagation of cells secreting monoclonal anti-idiotype antibodies, the characterization of these antibodies and their purification have been described previously⁸. A cell line designated A6.24 was isolated, cloned and propagated in (C57BL/6 × BALB/c)F₁ animals; it secreted large amounts of a

monoclonal anti-B1-8 antibody. The antibody was purified from ascites fluid by ammonium sulphate precipitation and subsequent chromatography on DEAE cellulose (DE52, Whatman) as described previously⁸. The purified material showed a single band in microzone electrophoresis, and on SDS-polyacrylamide electrophoresis¹² in reducing conditions, two main bands appeared in the position of immunoglobulin L and H chains. It typed as an IgG2a in an enzyme-linked immunosorbent assay¹¹. In radioactive binding assays antibody A6.24 reacted with the B1-8 protein and its Fab and Fv fragment⁸ and a fraction of C57BL/6 anti-NP serum antibodies (see below), but not with any of a series of myeloma proteins or, at a detectable level, with immunoglobulins from normal sera. The reaction of antibody A6.24 with B1-8 could be specifically blocked by an excess of NIP-BSA (4-hydroxy-5-iodo-3-nitrophenyl-bovine serum albumin) but not of NIP-caproic acid. Antibody A6.24 thus behaves as a typical anti-idiotype antibody detecting a group 2 idiotype in our previous nomenclature⁸. This idiotype is distinct from the idiotype defined by antibody Ac38, as antibodies A6.24 and Ac38 exhibit different patterns of reactivity with a series of NP-binding monoclonal antibodies (data not shown).

Antibody A6.24 is also distinguished from the previously used antibody Ac38 by its origin (C57BL/6) and by its class: it types as an IgG2a whereas Ac38 is an IgG1. How does injection of antibody A6.24 into C57BL/6 mice influence the expression of the corresponding idiotype (which we call idiotype A6.24) in the anti-NP response? Groups of age- and sex-matched C57BL/6 mice received 33 ng or 10 µg A6.24 intraperitoneally. Controls were injected with diluent alone. 2–8 weeks later the animals were immunized with NP₈-CG and bled 12 days later. The protocol of the experiment thus followed exactly that of our previous, analogous experiments (see above and ref. 6). The sera were titrated for total λ₁-bearing anti-NP antibodies and for idiotype A6.24. The results of these titrations appear in Fig. 3.

It can be seen that, as in the experiments with Ac38, 10 µg A6.24 profoundly suppresses the expression of the corresponding idiotype, leaving the total anti-NP response untouched. Suppression is almost complete throughout the entire experiment. However, at the 33-ng dose which would have led to maximal enhancement in the case of Ac38⁶, antibody A6.24 again produces suppression, although less pronounced than at the 10-µg dose. As previously⁶, there is an indication of oscillations of idiotype expression. The class distribution of the anti-NP antibodies in the sera from various groups of this experiment was also determined (data not shown). It was essentially the same as that in the experiment depicted in Fig. 2. Only idiotype-bearing IgG but not IgM antibodies were significantly suppressed.

Our data show that striking modulation of idiotype expression in an immune response can be achieved by the prior administration of an isologous, monoclonal anti-idiotype antibody. Thus, the capacity to recognize, respond against and regulate the expression of a given idiotype determinant exists within a single mouse strain. This strongly suggests that antibody-mediated network regulation is an important physiological process as discussed in detail elsewhere⁶. Our data also suggest that the effector function of isologous anti-idiotype antibodies in network regulation may be influenced by the heavy-chain constant region. Antibody Ac38, an IgG1, enhances and suppresses, depending on the dose. The same has been found for another IgG1 anti-idiotype, Ac146 (ref. 13). Antibody A6.24, an IgG2a, may only suppress. This is reminiscent of the previous finding that guinea pig IgG1 anti-idiotypic antibodies enhance idiotype expression in the mouse, whereas IgG2 has suppressive effects^{2,3}. At least in terms of their complement-fixing properties, IgG1 and IgG2 in mice and guinea pigs are similar^{14,15}. Clearly, however, our experiments can not formally assign distinct functions in network control to the constant regions of γ1 and γ2a heavy chains. It is known, for example, that different allelic forms of the γ2a chain may differ drastically from each other in primary structure (P. Schreier and

Fig. 2 Immunoglobulin class distribution of total and idiotype Ac38-bearing anti-NP antibodies in the sera of groups of mice injected with different doses of anti-idiotype antibody (Ac38) and subsequently immunized with 100 µg NP₈-CG. Each column represents the geometric mean ($\pm$ s.d.) of the amounts of anti-NP antibody of a particular immunoglobulin class expressed within a group of mice. That fraction of antibodies bearing the Ac38 idiotype is given by the shaded portion of each column. *a*, (CBA × C57BL/6)F₁ mice injected with 10 ng or 10 µg of Ac38 6 weeks before immunization with NP-CG. *b*, C57BL/6 mice injected with diluent, 100 ng Ac38, or 10 µg Ac38. Based on earlier results⁶, mice injected with 10 µg or 100 ng Ac38 were immunized with NP-CG 4 or 8 weeks later, respectively. Antibody concentrations were determined in a solid-phase radioimmunoassay⁶. To determine total anti-NP antibody, hapten-binding immunoglobulin was detected with ¹²⁵I-labelled, immunoglobulin class-specific antibodies (described in ref. 16). Those antibodies bearing the Ac38 idiotype were detected in a similar manner with the exception that the solid-phase coat was the F(ab)₂ fragment of antibody Ac38 rather than a hapten-protein conjugate. Absorption experiments showed that virtually all (>90%) idiotype Ac38-positive antibodies bound the NP hapten.

Fig. 3 Idiotope suppression induced by monoclonal anti-idiotope antibody A6.24. Groups of six mice were injected intraperitoneally with *a*, 33 ng (○, ●; unbroken lines) or *b*, 10 µg (△, ▲; unbroken lines) of antibody A6.24 and immunized 2–8 weeks later with NP-CG. Control mice (□, ■; broken lines) received diluent instead of anti-idiotope antibody. 12 days after the administration of antigen the animals were bled and the sera of individual mice analysed in a solid-phase radioimmunoassay⁶ for total, λ_1 -bearing anti-NP antibodies (open symbols) and λ_1 -bearing anti-NP antibodies expressing the A6.24 idiotope. The geometric means (with s.d.) of the antibody concentrations in the sera are plotted against the time between injection of anti-idiotope antibody and antigen.

A. Bothwell, personal communication). A definitive assignment will require the testing of a number of isologous anti-idiotope antibodies of various isotypes and (more importantly) the isolation of pairs of anti-idiotope antibodies with identical variable regions but belonging to different immunoglobulin classes, for example class-switch variants. A technique for the isolation of such pairs of antibodies is available¹⁶. Finally, it seems that the target of regulation by our anti-idiotope antibodies is mainly the IgG and not the IgM antibody response. It will be important to investigate the basis of this finding as regulatory studies with conventional isologous anti-idiotypic antisera suggest that in certain conditions, IgM and IgE responses can also be affected by idiotypic control^{4,17}.

Control of enzyme secretion by non-cholinergic, non-adrenergic nerves in guinea pig pancreas

G. T. Pearson, J. S. Davison, R. C. Collins & O. H. Petersen*

Department of Physiology, University of Dundee, Dundee DD1 4HN, UK

Depolarization of pancreatic cells by exposure to high potassium solutions is associated with release of amylase. In the guinea pig, but not the mouse or cat, this Ca-dependent amylase secretion is resistant to atropine blockade^{1–4}, thus Scheele and Haymovits^{3,4} concluded that the enzyme secretion evoked by K depolarization does not involve release of transmitter from intrapancreatic nerves but is a consequence of Ca uptake into acinar cells mediated by the membrane depolarization. This hypothesis is inconsistent with current concepts of stimulus–secretion coupling in electrically non-excitable cells⁵. The observation of Scheele and Haymovits could, however, also be explained by the release of a non-cholinergic, secretomotor transmitter as a consequence of the depolarization of intrapancreatic nerves. By adapting the technique of electrical field stimulation of isolated pancreatic segments^{6,7} to our studies of amylase secretion, we have now been able to demonstrate both cholinergic and non-cholinergic, non-adrenergic secretomotor nerves in the guinea pig pancreas. Excitation of the non-cholinergic nerves stimulates amylase secretion by a different intracellular coupling mechanism from that activated by cholinergic nerves or by peptides belonging to the cholecystikinin, gastrin or bombesin families⁸.

All experiments were done on isolated segments of guinea pig pancreas superfused with oxygenated physiological salt solutions at 37 °C (ref. 7). Amylase secretion from the pancreas was measured using an on-line automated fluorometric method⁹, intracellular recordings of acinar transmembrane potentials were obtained using glass microelectrodes⁷, and Ca efflux was monitored by measuring the release of ⁴⁵Ca from prelabelled tissue¹⁰.

Electrical field stimulation (FS) has recently been shown to be an effective method of exciting intrinsic nerves in the pancreas^{6,7}. Using Perspex flow cells incorporating silver electrodes, we have studied the effects of FS on membrane potentials, amylase secretion and ⁴⁵Ca²⁺ efflux. In preliminary experiments we confirmed the results of Scheele and Haymovits^{3,4} that an elevated extracellular K concentration (75 mM) stimulated amylase secretion even in the presence of atropine (10^{–5} M). This protocol, however, is unhelpful as it is impossible to distinguish between indirect effects mediated by depolarizing nerve endings and direct effects due to depolariza-

* To whom correspondence should be addressed.

tion of the acinar cells. The nerve-blocking drug tetrodotoxin (TTX) (10^{-6} M) did not abolish the effects, as also noted by Scheele and Haymovits⁴, but K depolarization of nerve endings might of course evoke transmitter release even in the absence of action potential formation. We decided, therefore, to investigate more directly the possible existence of non-cholinergic nerves.

Figure 1a shows FS-evoked amylase secretion from a tissue superfused with normal physiological solution. Addition of the muscarinic antagonist atropine (10^{-5} M), in a concentration sufficient to abolish maximum response to exogenous acetylcholine (ACh) stimulation (10^{-4} M), reduced, but did not abolish, the FS response. Such an atropine-resistant amylase

Fig. 1 Effects of electrical field stimulation (FS) on amylase release from superfused guinea pig pancreatic fragments. The figure shows two separate experiments (a and b) in which amylase in the effluent from the tissue chamber (1 ml vol, flow rate 1 ml min⁻¹) was continuously assayed by an automated fluorometric, on-line method⁹. FS, for the duration indicated, was achieved by connecting silver electrodes in the chamber to an isolated stimulator. Stimulation parameters were the same throughout: 20 Hz frequency, 50 V amplitude, 1 ms pulse width for 5 min. (FS using these parameters, even for periods up to 20 min, did not cause any change in the pH of the Krebs solution flowing through the tissue chamber.) The three panels in a are consecutive traces from the same experiment showing the effects of FS on the amylase concentration in the tissue chamber effluent during exposure of the tissue to a normal physiological salt solution, in the presence of atropine (10^{-5} M) and in the presence of both atropine (10^{-5} M) and TTX (10^{-6} M); b shows the FS response in the presence of both atropine (10^{-5} M) and guanethidine (10^{-5} M). All drugs applied were present in the superfusing solution for a minimum period of 20 min before FS. Note the different calibrations (2 units of amylase ml⁻¹) in a and b.

Fig. 2 Recording of guinea pig acinar cell membrane potential. An isolated segment of pancreas was secured to a Perspex platform and superfused with oxygenated physiological salt solution at 37 °C. A single microelectrode filled with 3 M KCl was inserted in an acinar cell to record a resting membrane potential of -35 mV. FS, as described in detail elsewhere⁷, was achieved using a pair of silver wire electrodes placed in contact with the tissue on the Perspex platform. These were connected to an isolated stimulator and the stimulation parameters throughout the experiment were 40 Hz, 30 V, 1 ms for 5 s. The effect of FS on the cell membrane potential is seen both in the absence and presence of atropine (10^{-5} M). At the arrow the solution flowing into the bath contained 10^{-5} M atropine for only ~10 s, thus the bath concentration of atropine is unlikely to have attained the 10^{-5} M concentration. Nevertheless, as seen in the trace, the FS effect was abolished. The response, however, rapidly returned and subsequent, sustained exposure to 10^{-5} M atropine (bar) again abolished the effect of FS. The break in the recording represents a 2-min interval.

secretion has been observed in 16 separate guinea pig preparations. Subsequent addition of TTX in a concentration that does not affect ACh or caerulein responses in the pancreas⁷ completely abolished the effect of FS. Abolition of the atropine-resistant FS response by TTX was observed in all six preparations tested, indicating that FS causes amylase release by initiating action potentials in intrapancreatic nerves. The adrenergic neurone-blocking drug, guanethidine (10^{-5} M), had no effect on the nerve-mediated amylase secretion in the five preparations tested (Fig. 1b), suggesting that the non-cholinergic response is not mediated by stimulation of adrenergic nerves. Furthermore, we have been unable to demonstrate any effect of noradrenaline (6×10^{-5} M) on amylase secretion. Although most experiments measuring nerve-mediated amylase secretion have been done using FS at 20 Hz frequency, effects have been observed at frequencies as low as 5 Hz. The mean value ($\pm$ s.e.m.) for FS-evoked amylase release at 20 Hz in the presence of atropine was $0.45(\pm 0.06)$ U per ml per 100 mg ($n=10$), corresponding to 20% of the mean value for the maximal secretion evoked by exogenous ACh (10^{-4} M). We conclude that the amylase secretion evoked by FS in the presence of atropine (Fig. 1) is mediated by excitation of intrapancreatic nerves, releasing a transmitter substance which activates the pancreatic acinar cells. The transmitter is not ACh and there is no indication that it is a catecholamine.

To test the functional innervation of individual acinar units⁷, membrane potential changes in response to FS were studied. Figure 2 shows examples of membrane depolarizations evoked by FS (40 Hz). Of 84 units studied, only 23 responded to FS, in marked contrast to the 100% effectiveness in the mouse⁷ and rat pancreas¹¹. The FS-evoked depolarizations, shown in Fig. 2, are always abolished by atropine (five preparations). It seems, therefore, that the transmitter released by excitation of the non-cholinergic, non-adrenergic nerves is unable to evoke membrane depolarization in spite of being a potent secretagogue.

The pancreatic secretagogues evoking enzyme secretion mediated by changes in cellular calcium metabolism (for example, ACh, cholecystokinin and bombesin) also cause acinar cell depolarization, while the secretagogue secretin (or vasoactive intestinal polypeptide, VIP) has no effect on ⁴⁵Ca fluxes or membrane electrophysiological parameters^{8,12,13}. We therefore tested the ability of FS to alter calcium metabolism in the guinea pig pancreas.

In the absence of atropine, FS caused a clear increase in fractional ^{45}Ca efflux from preloaded pancreatic segments in two separate experiments (Fig. 3). In the presence of atropine, however, the same type of FS (20 Hz, 40 V, 1 ms) failed to evoke any measurable effect on ^{45}Ca efflux in the four different preparations tested, although all of these responded with a marked increase in ^{45}Ca outflux when subsequently challenged with caerulein (1.5×10^{-9} M, Fig. 3).

The nerve-mediated secretion obtained in the presence of atropine (Fig. 1) is clearly not associated with membrane depolarization (Fig. 2) or with an increase in ^{45}Ca efflux (Fig. 3). The as yet unidentified transmitter substance is therefore unlikely to be a peptide belonging to the cholecystokinin-gastrin-caerulein, bombesin or substance P families because all secretagogues studied from these groups characteristically evoke marked Ca outflux and membrane electrical changes^{8,12,13}.

Fig. 3 The effect of FS and the secretagogues caerulein (Cn) and acetylcholine (ACh) on the fractional efflux of ^{45}Ca from preloaded superfused fragments of guinea pig pancreas. The pancreatic segments were loaded for 60 min in 2 ml of physiological salt solution containing $10 \mu\text{Ci } ^{45}\text{Ca}$ and maintained at 37°C . The procedure was similar to that described elsewhere¹⁰. After loading, the segments were transferred to a flow cell. In each experiment the tissue was superfused for 150 min before collection of effluent samples, which were subsequently analysed in a scintillation counter. Values for concentration of radioactivity in the samples taken at different time points together with the value for the radioactivity remaining in the tissue at the end of the experiment were processed by computer (MINC-11, Digital). Values were obtained for fractional efflux ($\Delta x / \Delta t x_i \text{ min}^{-1}$, where x represents c.p.m. ^{45}Ca released in the time interval Δt and x_i the tissue ^{45}Ca content at the midpoint of interval Δt) as a function of time. FS was carried out in exactly the same way as described for the amylase studies. Stimulation parameters were similar in each experiment: 20 Hz, 40 V, 1 ms for 5 min. Cn (1.5×10^{-9} M) and ACh (10^{-5} M) were added to the superfusing solution for the periods indicated by the bars. Atropine (10^{-5} M) was present throughout the experiment shown in the lower panel. Upper panel, normal preparation.

The present study has demonstrated, for the first time, the existence of non-cholinergic, non-adrenergic nerves controlling pancreatic acinar enzyme secretion. Its importance lies in the widespread distribution of non-cholinergic, non-adrenergic nerves throughout the peripheral autonomic nervous system^{14,15}. The transmitter released from the non-cholinergic, non-adrenergic nerves in our experiments might be VIP or a related peptide, as VIP-immunoreactive nerves have been demonstrated in the pancreas^{16,17}. VIP is known to stimulate amylase secretion by a mechanism not involving changes in cellular Ca metabolism^{8,13}.

Our results also resolve an important controversy in the discussion of pancreatic stimulus-secretion coupling⁸ because the Ca-dependent depolarization-evoked enzyme secretion observed in the presence of atropine^{3,4} can now most conveniently be explained as being due to Ca-dependent secretion of a neurotransmitter that interestingly does not seem to activate secretion through changes in cellular calcium metabolism.

Transforming genes of carcinomas and neuroblastomas introduced into mouse fibroblasts

Chiaho Shih, L. C. Padhy, Mark Murray & Robert A. Weinberg

Department of Biology and Center for Cancer Research, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

We have previously¹ demonstrated that DNA of mouse fibroblasts transformed by 3-methylcholanthrene (3-MC) induced foci of transformed cells when applied to monolayer cultures of NIH3T3 cells, which indicates that at least a part of this phenotype is encoded in DNA sequences. However, our conclusions were confined to the effects of DNAs of 3-MC-transformed mouse fibroblasts on recipient NIH3T3 cells, also of mouse fibroblast origin. To elucidate this phenomenon further, we have prepared DNAs from a series of mouse and non-mouse tumour lines of non-fibroblastic origin and investigated whether tumour transforming genes can act across tissue and species barriers to transform NIH3T3 cells. We find that DNAs obtained from human, rabbit and mouse bladder carcinoma lines, a lung carcinoma line and rat neuroblastoma and mouse glioma lines, are able to induce transformation of NIH3T3 cells on transfection.

DNAs prepared from tumours or tumour cell lines were transfected using the calcium phosphate transfection procedure described elsewhere^{1,2}. Each transfected culture was passaged into 12 subcultures and foci of transformants were scored 14–20 days later¹; only foci containing very refractile cells were counted. Because of occasional ambiguities in resolving true transformants from spontaneous overgrowths of the monolayer culture, critical transfections were scored using a double-blind protocol. We observed induction of transformed foci when transfected DNAs were prepared from two classes of tumour cells: neuroblastoma/glioma (Table 1) and carcinoma (Table 2).

Most of the DNAs used in these experiments were prepared from tumour cell lines which had been derived from tumour explants. Each tumour cell line that gave positive results had been shown to possess differentiation markers characteristic of the tumour type from which the cell line had been derived^{3–8}. For example, the neuroblastoma lines had been shown to have excitable membranes, neurite extensions and neurotransmitter enzymes³; tumours induced by cell lines of carcinoma origin possessed keratin and characteristic acinar structures⁵.

As seen in Table 1, foci were induced by the DNAs of one glioma and three neuroblastoma cell lines. The latter were derived from tumours induced in rats *in utero* by exposure to ethylnitrosourea³, and the glioma cell was prepared from a tumour induced by direct implantation of a 3-MC precipitate into the brain of a newborn mouse⁴. The foci produced by these transfections were grown up and their DNA prepared for a second cycle of transfection. The DNAs of these primary foci were all able to induce secondary foci, which demonstrates the serial transmissibility of these transformation-inducing sequences.

Transfection of the DNAs of three different bladder carcinoma cell lines also yielded foci after application to NIH3T3 monolayer cultures as did transfection of DNAs of the mouse Lewis lung carcinoma tumour (Table 2). Again, DNAs prepared from cultures of these primary transfectants were able to induce foci after a second cycle of transfection. The DNAs of a large series of other carcinoma cell lines yielded few or no foci on transfection (Table 2).

When the cells of foci resulting from transfections induced by neuroblastoma, glioma and carcinoma DNAs were grown into mass cultures and seeded subcutaneously into newborn NFS mice, rapidly growing fibrosarcoma-like tumours were observed

after 2 weeks with almost 100% incidence (Tables 1 and 2). Thus, the transfected DNA induced foci of cells which were highly tumorigenic. In contrast, normal, untransfected NIH3T3 cells resulted in a low incidence of tumours (1/7, 1/10) which only appeared 4 weeks after subcutaneous injection into the newborn mice (Tables 1, 2).

All attempts at rescue of C-type transforming retroviruses from the transfected cells were unsuccessful. We also attempted rescue of virus from cells transformed by Moloney sarcoma virus and observed the release of high titres of focus-forming virus. We conclude that transmissible C-type viruses are not responsible for the phenomenon of focus induction in donor or recipient cells.

Human donor DNA was used in one of these transfections to obtain direct biochemical proof that the transfected cells had taken up and stabilized human DNA. This depended on the fact that the few cells which acquire a selected marker gene also acquire a large number of other donor DNA fragments which enter the cells during the same transfection event⁹. In contrast, other cells in the culture which have not acquired the selected marker gene do not show this array of co-transfected donor sequences⁹.

In the present study, cells which have acquired the human bladder carcinoma transformation gene should also contain a large array of other co-transfected human DNA fragments, many of which should bear a copy of a highly repeated (300,000 per haploid) sequence which is interspersed throughout the human genome¹⁰. This sequence is not detectable in normal mouse DNA. Such sequences can be detected by the Southern blot procedure¹¹ using a cloned probe of the highly repeated human sequence^{10,12}. Figure 1, lanes c–g, reveals the presence of many segments bearing the human repeated sequence in the DNAs of five different cell lines, each derived from a separate focus induced by human bladder carcinoma DNA. DNAs not derived from *bona fide* transfectants show no trace of these acquired human sequences (lanes a, b). The successfully transformed cells are thus descended from the small subpopulation of cells in the initially transfected culture⁹ which was able to take up and fix large amounts of donor DNA. We conclude that the transformation of these cells was a direct consequence of the acquisition of sequences of a human bladder carcinoma DNA. This or similar hybridization tests may be used as assays to distinguish *bona fide* transfectants from other

Table 1 Transfection of DNAs of glioma and neuroblastoma cell lines

Donor DNA	Tissue type, strain and species	Mode of tumour induction	Efficiency of primary transfection (FFU per 75 µg DNA)	Efficiency of secondary transfection (FFU per 75 µg DNA)	Tumorigenicity of primary transfectant	Retrovirus rescue assay of primary transfectant
G26-20	C57BL/6 mouse glial*	3-methylcholanthrene precipitate was implanted directly into mouse brain	10†	16†, 22†	ND	ND
NIH3T3	NIH/Swiss embryo		0†		1/10‡, 1/7‡	0
B50	BDIX rat, neurone§	Fetal rats were exposed to nitrosoethylurea transplacentally	6, 9, 13, 16	78, 82†, 100†	8/8	0
B104	Same		9, 31	500	6/6, 7/7	0
B103	Same	by injection into pregnant mother on day 15 after conception	93, 122†	12†, 12†	9/9	0
B65	Same		0, 0–1, 0†			
B15	BDIX rat, glial		0†, 0†, 1			

One transfection (fourth and fifth columns) is defined as 75 µg DNA applied to 1.5×10^6 NIH3T3 cells and values represent total number of foci per transfection. Transfection procedures were as described elsewhere¹. Tumorigenicity of transfectant clones was determined by injecting subcutaneously $1-2 \times 10^6$ cells suspended in 0.1 ml PBS into 1–2-day-old newborn mice of NFS or NIH/Swiss outbred strains. Tumour formation was seen after 2 weeks. NIH3T3 cells were injected in an identical manner as a control. Retrovirus rescue assays were designed to induce the release of any defective, transforming viruses which might be present in the transfected cultures as described elsewhere¹. The titre of helper virus released from infected cultures in these rescue assays was routinely 1×10^7 plaque forming units per ml. Infection of Moloney murine sarcoma virus-transformed NIH3T3 non-producer cells with helper virus, performed in parallel as positive control, resulted in release of $>5 \times 10^3$ focus forming units (FFU) of transforming virus per ml. Lines B65 and B15 were used as negative controls for the transfection assay. ND, not determined. IMR32 human neuroblastoma¹³ and NB2A (c1300) mouse neuroblastoma¹⁴ DNAs did not induce a significant number of foci.

* See ref. 15 for origin.

† Not performed in double-blind.

‡ These tumours were seen only at 4 weeks post-inoculation.

§ See ref. 3 for origin.

Table 2 Transfection of DNAs of carcinoma and other tumour lines

Donor DNA	Tissue type, strain and species	Mode of tumour induction	Efficiency of primary transfection (FFU per 75 µg DNA)	Efficiency of secondary transfection (FFU per 75 µg DNA)	Tumorigenicity of primary transfectants	Retrovirus rescue assay of primary transfectant
Lewis lung carcinoma tumour	C57BL/6 mouse lung epithelial*	Spontaneously occurring in animal	7†, 12, 13, 66	95, 105†	9/9	0

Human epidermal cell strain	Human epidermis		0†, 0†			

DNA transfection procedures were as described elsewhere¹; one transfection is defined as 75 µg DNA for 1.5×10^6 NIH3T3 recipients. Tumorigenicity and retrovirus rescue assay were carried out as described in Table 1 legend. The DNAs of the following tumour cell lines induced few or no foci in a transfection assay: SCC9, SCC12X, SCC4 squamous cell carcinoma cell lines¹⁶; A1663 a human bladder carcinoma line¹⁷; A549, a human lung carcinoma line¹⁷; Detroit 562, a human pharyngeal carcinoma line¹⁸; RT4, a human bladder carcinoma line¹⁹; BC6 a rat bladder carcinoma line (obtained from Dr Howard Green, MIT); and Nettesheim squamous cell carcinoma (obtained from A. D. Little Co.). The DNAs of other tumour cell lines induced few or no foci in a DNA transfection assay: HTC rat hepatoma established by Dr Gordon Tomkins; 7777 rat hepatoma²⁰; human Murawski melanoma and human Wolfe melanoma (obtained from Dr Lloyd Old); A375 human melanoma¹⁷; M3 mouse melanoma²¹ and B16 mouse melanoma²².

*For information on origin of cell line see Dr M. R. Lewis, unpublished data.

† Not performed in double-blind.

colonies in cultures which have become transformed by mechanisms other than transfection.

The positive results with the human, rabbit and rat tumour DNAs indicate that tumour transforming genes are able to act across species barriers—they may also act across tissue barriers: for example, transforming sequences of neuroblasts and epithelial cells can transform the recipient fibroblasts. In addition, transforming sequences that are active in these transfections (Tables 1, 2) may be derived from tumours induced by a variety of carcinogens which have been administered in different ways. We conclude that the transfection assay can reveal transformation sequences in tumours of diverse origin and is therefore not limited to analysis of donor tumour DNAs of mouse fibroblast origin. The demonstration of these transmissible genes from various tumours will allow their molecular cloning

and the analysis of the molecular basis of non-viral carcinogenesis.

We thank the following people for providing tumour cell lines: Drs I. Summerhayes, L. B. Chen, J. Rheinwald, H. Green, O. Kehinde, J. Patrick, T. Yean-Kai, I. Wodinsky, G. Todaro,

Fig. 1 Detection of human DNA sequences in transformed NIH3T3 cells following transfection with EJ carcinoma DNA. DNA was prepared from five foci; 10 µg of each DNA was digested with *Eco*RI and electrophoresed through a 1% agarose gel in 40 mM Tris (pH 7.9), 50 mM sodium acetate and 1 mM EDTA. The gel was run at 1.2 V cm^{-1} for 16 h. After electrophoresis, the DNA was transferred to nitrocellulose by the method of Southern¹¹, and the resulting blot hybridized with the BLUR8 clone of the human repetitive 'Alu family' DNA¹². The Alu probe was ³²P-labelled by nick translation²³ and 5×10^6 c.p.m. of labelled probe was hybridized to the blot in the presence of 10% dextran sulphate²⁴. Hybridization was carried out for 40 h followed by a 12-h exposure to X-ray film. Whole cellular human DNA used as a positive control gave extensive blackening throughout the entire lane, without discernible bands (not shown here). Approximate size ranges (in kilobases) are indicated to the right of the gel. a, b, DNAs of untransformed NIH3T3 cells, picked and cloned from dishes which also contained transformed foci. c-g, DNAs from different transformed foci of NIH3T3 cells, derived from transfection of EJ donor DNA.

L. Old, J. Fogh, T.-W. Chang and C. Cepko; Drs P. Deininger, C. Schmid and W. Jelinek for the BLUR8 clone; Dr James Murphy for histology of several tumour samples. We also thank A. Dannenberg and H.-W. Hsu for technical assistance and Dr B. Shilo for useful discussions. This work was supported by funds from the Rita Allen Foundation of New York and the NIH, including core grant CA14051 and program project CA26717. C.S. was supported by a training grant to the MIT Department of Biology, L.C.P. was the recipient of an Eleanor Roosevelt International Fellow and M.M. was a fellow of the Damon Runyon-Walter Winchell Foundation.

Identification of mutations affecting replication control of plasmid Clo DF13

Antoine R. Stuitje, Cornelis E. Spelt, Eduard Veltkamp & H. John J. Nijkamp

Department of Genetics, Biological Laboratory, Vrije Universiteit, De Boelelaan 1087, 1007 MC Amsterdam, The Netherlands

The bacteriocinogenic plasmid Clo DF13, originally isolated from *Enterobacter cloacae*¹, is stably maintained in *Escherichia coli*² to the extent of about 10 copies per cell³. Its replication⁴ resembles that of many other small, multicopy plasmids⁵⁻⁸; plasmid-encoded protein is not required⁹⁻¹² but plasmid-specific genetic information is involved in regulation of replication as both conditional¹³ and nonconditional³ copy-number mutants of Clo DF13, and transcomplementable^{14,15} copy-number mutants of plasmid Col E1 have been described. The sequences essential for replication of Col E1 (refs 16, 17) and Clo DF13 (refs 18, 19) have been identified within a region surrounding the replication origin. Initiation of Col E1 replication is preceded by transcription of the origin region, providing the RNA primer at the origin²⁰. However, transcription in the opposite direction results in a small transcript of ~100 nucleotides (RNA-100) for both Col E1 (refs 21, 22) and Clo DF13 (ref. 23). Data suggest that Col E1 RNA-100 acts as a negative control element for the initiation of replication^{20,24}. We show here that single base transitions in the RNA-100 cistron of Clo DF13 can result in a nonconditional increase in plasmid copy-number. Also, sequence analysis has revealed that a specific base transition in a DNA region, apparently involved in both termination and initiation of transcription towards the replication origin, results in a thermosensitive plasmid copy-number.

Both nonconditional³ and conditional¹³ replication-control mutants of plasmid Clo DF13 (8.6 kilobases) have been isolated after chemical mutagenesis, and characterized^{13,25}. As reported elsewhere¹⁸, the Clo DF13-*cop3* mutation (Table 1) was mapped by insertion of transposons and successive deletion of specific restriction fragments. Similar studies on the Clo DF13-*cop1* (Ts) and the Clo DF13-*cop2* mutants (Table 1) show that these mutations are also located within the region (1.8-15%) surrounding the replication origin. These copy mutations were localized more precisely within this region by *in vitro* recombination experiments (see Fig. 1 legend). Subsequently, specific regions of the different copy mutants were sequenced as indicated in Table 1. By comparing these sequences, the complete nucleotide sequence between the *Hae*II site at 1.8% and the *Bam*HI site at 15% was deduced (Fig. 2). Furthermore these studies show that these different *cop* mutations are, in fact, point mutations, and all represent base transitions (Fig. 2).

Recently, Itoh and Tomizawa²⁰ demonstrated that the initiation of DNA replication of plasmid Col E1 *in vitro* is preceded by transcription of the origin region, towards the origin of replication, generating a precursor primer RNA molecule (Fig. 1). Furthermore, they showed that when transcription passes the origin, the RNA transcript is able to form a stable hybrid with this region. In the next step RNase H specifically cleaves the hybridized RNA, producing the RNA-DNA hybrid with a free 3' OH end for the initiation of DNA replication by DNA polymerase I. The 5' end of the 'pre-primer' RNA has been sequenced and the corresponding region within the sequence of plasmid Clo DF13 is indicated in Fig. 2.

Figures 2 and 3 show that the Clo DF13 *cop1* (Ts) mutation involves a base transition at position 720. The region surrounding this mutation has several interesting features: first, the nucleotide sequence of this region (see Fig. 4b) resembles that of regions known to be involved in termination of transcription²⁶. A similar role for the region in Clo DF13 is supported by data²³ which shows that transcription from the cloacin promoter results in the synthesis of two RNA molecules of 2.2 and 2.4 kilobases respectively. The terminator for the transcription resulting in the synthesis of the 2.4-kilobase RNA was located at 9.3%, and therefore maps within the sequence mentioned above (T2, Fig. 1). Second, the nucleotide sequence of the region surrounding the *cop1* (Ts) mutation (position 696-735) is completely conserved when compared with the corresponding sequence of plasmid Col E1 (ref. 16). The position of the initiation site of transcription of the Col E1 pre-primer RNA, as determined by Itoh and Tomizawa²⁰, implicates the Col E1 region mentioned above in promotion of the synthesis of this RNA. Therefore, the corresponding region of plasmid Clo DF13 which surrounds the *cop1* (Ts) mutation might also act as promoter for RNA synthesis (P3, Fig. 1). In view of these data, the *cop1* (Ts) mutation could be a promoter-type or terminator-type mutation. Alternatively, it could be a mutation at the site of action of a control element. Further experiments are in progress to discriminate between these possibilities and determine whether the effect of the *cop1* (Ts) mutation, a temperature-inducible increase of the plasmid copy-number, is caused by an increased synthesis of pre-primer RNA at the elevated temperature.

The nonconditional *cop2* and *cop3* mutations are located within a Clo DF13 region which is transcribed *in vivo* and *in vitro* resulting in a RNA molecule of ~100 nucleotides^{19,23} (RNA-100, see Figs 2, 3). The corresponding region of plasmid Col E1 is also transcribed *in vitro*^{21,22}, producing a similar molecule. The nucleotide sequence of the latter RNA-100 species has been determined and is indicated in Fig. 4a. Perusal of the Clo DF13 and Col E1 sequences encoding this RNA-100 species strongly suggest that these RNA molecules are not translated. Furthermore, it was observed that although the primary structures of the Clo DF13 and Col E1 RNA-100 species differ largely, the secondary structure seems to be highly conserved (Fig. 4a). The position of the *cop2* and *cop3* mutations within the sequence (Fig. 2) makes it unlikely that these mutations directly affect the synthesis of either the RNA-100 or the pre-primer RNA.

Fig. 1 Detailed physical/genetic map of the region between the *HaeII* site and the *BamHI* site at respectively 1.8 and 15% on the Clo DF13 map¹⁹. The positions of the various restriction endonuclease cleavage sites were determined as reported previously¹⁹ and verified by sequence analysis. The exact position of the immunity gene (*imm*) could be determined by DNA sequence analysis of this region, as part of the amino acid sequence of the Clo DF13 immunity protein has been elucidated²⁷. The region of the Clo DF13 plasmid genome encoding the H protein was previously described²³. The nucleotide sequence probably encoding this polypeptide of about 50 amino acids is indicated in Fig. 2. The region possibly encoding an arginine-rich, basic polypeptide of about 45 amino acids, for both Col E1 and Clo DF13 (ref. 19), is indicated as 'gene?'. As reported²³, transcription initiated at the cloacin promoter (P1) terminates at t1 or t2 resulting in RNA molecules of ~2,200 and 2,400 nucleotides respectively. By comparing the Clo DF13 and Col E1 origin sequences, the position of the Clo DF13 RNA-100 cistron was deduced¹⁹. As indicated, the origin of replication maps within the 1.8–5% *HaeII* restriction fragment²⁸. By partial cleavage of a Clo DF13-*cop3* derivative (pEV26)¹⁸ with *HaeII* endonuclease in the presence of S₁ nuclease, followed by ligation with T₄ ligase and transformation of *E. coli*, we have isolated a plasmid which has an altered *HaeII* (1.8–5%) 'origin' fragment and still contains the *cop3* mutation (A.R.S. *et al.*, unpublished results). Recombinant plasmids containing both wild-type (wt) and *cop3 HaeII* fragments were obtained by transforming cells to ampicillin resistance with a ligated mixture of wild-type and *cop3 HaeII* fragments. The composition of the recombinant plasmids was easily determined from the *HaeII* digestion patterns. The Cop phenotype was deduced from the minimal inhibitory concentration of ampicillin of cells harbouring these plasmids. By these types of study the Clo DF13-*cop3* and -*cop2* mutations were localized more precisely within the 1.8–15% origin region (see Table 1).

Fig. 2 The nucleotide sequence of the Clo DF13 region between the *Hae*II site at 1.8% and the *Bam*HI site at 15% on the Clo DF13 physical map (see also Fig. 1). The sequencing procedures were as described previously¹⁹. The sequence strategy is indicated in Fig. 1 legend; the arrows in Fig. 1 show the part of the restriction fragments sequenced. The direction of the arrows indicates the strands which were sequenced, aligned in 5' to 3' direction (tail to head). Start and stop indicate respectively the start and stop codons for proteins; 'ini' and 'term' represent the 5' and 3' ends of RNAs respectively.

Table 1 Properties of Clo DF13 and mutant plasmids

Plasmid	Derivation	Relevant properties	Copies per cell	MW (kilobases)	Clo DF13 region present (%)	Map* position of the <i>cop</i> mutation (%)	Clo DF13 region of plasmid sequence (%)	Ref. source
Clo DF13	Naturally occurring in <i>E. cloacae</i>	Cloacin DF13	10	8.6	0–100	—	—	1
Clo DF13- <i>cop3</i>	Clo DF13	Cloacin DF13, nonconditional copy mutant	70	8.6	0–100	5–11.5	—	21
Clo DF13- <i>cop2</i>	pEV5	Nonconditional copy mutant, Ap	200	2.9	1.8–15	5–15	5–15	Stuitje (unpublished)
Clo DF13- <i>cop1</i> (Ts)	pJN03	Cloacin DF13, ApTs-copy mutant Ts-kill	Temperature dependence	13.1	0–100	1.8–9.5		14
pEV5	Clo DF13::Tn901 insertion mutant	Ap	10	2.9	1.8–15		5–15	Stuitje (unpublished)
pEV22	Clo DF13- <i>cop3</i> ::Tn901 insertion mutant	Ap	200	2.8	1.8–11.5		1.8–11.5	4
pVU206	Clo DF13- <i>cop1</i> (Ts)	Ap Ts-copy mutant Ts-kill	Temperature dependence	3.3	1.8–15 27–29		1.8–15	Stuitje (unpublished)

Ts, temperature sensitive.

* The different *cop* mutations were localized more precisely within the 1.8–15% origin region by recombining the *Hae*II 'ori' fragments of the different mutant plasmids, as described in Fig. 1 legend.

Although our data on the *cop2* and *cop3* mutations do not exclude a possible role of the RNA-100 as a positive control element, they are consistent with previous findings that favour the RNA-100 as a negative control element for the initiation of DNA replication^{20,24}. Furthermore, results²⁵ suggest that the RNA-100 is involved in plasmid incompatibility, a plasmid function that seems to be intimately connected with replication control. In fact, it has been reported²⁰ that the presence of the RNA-100 species of plasmids belonging to the Col E1 incompatibility group inhibits the formation of the primer *in vitro*. The sequence data described in this letter indicate that there are at least two distinct regions that are important in the control of Clo DF13 replication. The first encodes a RNA-100 molecule whose synthesis is initiated ~490 nucleotides upstream from the replication origin, whereas the second, which is located about 620 nucleotides upstream from the origin,

seems to be involved in both termination and initiation of transcription towards the origin. The identification of the different mutations inevitably evokes questions on the mechanism of replication control of small plasmids such as Col E1, for example: (1) is the frequency of initiation of DNA replication controlled at the level of pre-primer RNA synthesis; (2) is the synthesis of pre-primer RNA regulated at P3/t2 (see Fig. 1); (3) in which way does the RNA-100 species control plasmid replication and are, in addition to this RNA, other plasmid-encoded gene products involved? Studies on additional copy-control mutants, including complementation experiments between the mutants and studies on the effects of alterations generated *in vitro* by substitution or deletion of specific sequences at different regulatory sites, may elucidate the actual mechanism of plasmid DNA replication control.

Fig. 3 *a*, Result of the Gilbert-Maxam sequencing procedure applied to fragment A (labelled at the 5' end of the *Hpa*II site as described previously¹⁹; see Fig. 1) derived from the wild-type (wt) Clo DF13 and the *cop2* and *cop3* mutants. Note the depression in the wild-type sequence near the position of the *cop3* mutation. The actual wild-type sequence 5'-A-A-A-G-C-C-A-3', instead of 5'-A-A-A-G-C-A-3', was deduced by sequence analysis of the complementary strand. *b*, Result of the Maxam-Gilbert sequencing procedure applied to fragment B (5' end-labelled at the *Hpa*II site; see Fig. 1) of the wild-type Clo DF13 plasmid and the Clo DF13-*cop1* (Ts) mutant.

Fig. 4 *a*, Comparison of the secondary structures of the RNA-100 species encoded by the plasmids Col E1 and Clo DF13. The resident *cop2* (C → U) and *cop3* (G → A) mutations are indicated. The most stable secondary structure was estimated by the procedure described by Tinoco *et al.*²⁹ and the ΔG (25°C) values estimated for the wild-type (wt) Clo DF13, *cop2*, *cop3* and Col E1: 100-nucleotide RNAs are respectively 50.4, -50.2, -41.2 and -45.6 kcal. *b*, Secondary structure of the DNA region surrounding the *cop1* (Ts) mutation (G → A transition). This region is presumed to be involved in both termination and initiation of transcription towards the origin (transcription proceeds from left to right). The sequences which are supposed to be involved in recognition and binding of RNA polymerase are indicated by -35 and -10 homology respectively²⁶.

This study was supported in part by The Netherlands Foundation for Chemical Research (SON) with financial aid from The Netherlands Organization for Advancement of Pure Science.

Differential usage of iso-accepting tRNA^{Ser} species in silk glands of *Bombyx mori*

Danièle Hentzen, Anna Chevallier & Jean-Pierre Garel

Department of General and Applied Biology, Université Claude Bernard, Lyon I, 43, Bd du 11 Novembre 1918, F-69622 Villeurbanne Cedex, France

The rapid development of the silk glands of *Bombyx mori* during the last larval instar shows two phases. During the first 4 days, in both the middle and posterior parts of the silk glands, the ribosomal machinery is assembled and the synthesis of house-keeping proteins starts. During the second phase (the last 4 days), the middle part of the gland synthesizes ~45 mg of the silk protein sericin (31% serine) and the posterior part of the gland synthesizes ~130 mg of the silk protein fibroin (46% glycine, 29% alanine and 12% serine). Silk fibroin and sericin are detectable by the second day and represent 80 and 50% respectively of the total proteins produced at day 8 (refs 1–4). It is known that the tRNA population of the posterior part of the gland is quantitatively adapted to fibroin codon frequency during this period^{5–9} but little is known about the situation in the middle part except for the observation that it contains more tRNA^{Ser} than does the posterior part. We show here that the two parts contain, and presumably use, different iso-accepting species of tRNA^{Ser}, the middle part using tRNA₁^{Ser}, which recognizes AGU and AGC codons, and the posterior part using tRNA₂^{Ser} which recognizes UCA. We also suggest that this differential adaptation of the tRNA^{Ser} species is under transcriptional control as the two species are accumulated at different rates, but degraded at the same rate.

tRNA^{Ser} species were fractionated and quantitated using benzoylated DEAE (BD)-cellulose chromatography¹⁰. Figure 1 shows chromatographic profiles of acylated Ser-tRNA from middle and posterior silk glands of *B. mori* at two different stages of development: the growth phase (day 2) and at the end of silk secretion (day 8). A striking difference occurs in the distribution of the subsets of tRNA^{Ser} species: in the fibroin-producing part, the tRNA₂^{Ser} group is predominant (82% during the secretion phase) but in the sericin-producing compartment, the tRNA₂^{Ser}/tRNA₁^{Ser} ratio changes from 3.1 at the start of the growth phase to 1.8 during the secretion phase. The tRNA₁^{Ser} species then represents 36% of the iso-tRNA^{Ser} family. From base composition, codon recognition and partial sequencing, we know that the tRNA₁^{Ser} species is capable of translating AGU and AGC codons, whereas the tRNA₂^{Ser} group recognizes UCA codons^{6,11,12}.

Refinements were made using two-dimensional polyacrylamide gel electrophoresis^{13,14}. As shown in Fig. 2, five spots can be assigned to iso-tRNA^{Ser} species. The tRNA₂^{Ser} subset fractionates according to the diagonal into three species: two tRNA_{2a}^{Ser} subspecies with the lowest mobility and one tRNA_{2b}^{Ser} with the highest mobility (Fig. 2*a*); tRNA₁^{Ser} migrates with an intermediate mobility. It seems to be heterogeneous and resolves into two distinct spots (Fig. 2*b–d*). Cross-identifications using purified tRNA^{Ser} species collected from a specifically retarded elution on BD-cellulose chromatography, done in the absence of Mg²⁺ ions¹⁵, yield the final pattern shown in Fig. 2*c, d*. The differential accumulation of iso-tRNA^{Ser} species is made clear on the electrophoretic maps in Fig. 3. It can be seen that the tRNA₁^{Ser} species is more abundant in the middle silk gland (MSG) than in the posterior silk gland (PSG) during the silk secretion phase. Polyacrylamide electrophoresis corroborates the BD-cellulose chromatographic profiles. An unexpected result was the unusual composition of the tRNA₂^{Ser} subset. tRNA_{2b}^{Ser} carrying the IGA anticodon is usually the major

Fig. 1 Chromatography on BD-cellulose of Ser-tRNA from posterior (PSG) and middle (MSG) silk glands of *B. mori* silkworm. *a*, Elution profiles of tRNA extracted from the middle part on the second day (growth phase) of the fifth larval instar and acylated with ^3H -serine ($\bullet$), and tRNA from the posterior part acylated with ^{14}C -serine ($\blacktriangledown$). The co-chromatography was achieved on a 40×2.2 cm BD-cellulose column eluted with a linear gradient of 0.2–1.0 M NaCl in 2 l of buffer: 10 mM sodium acetate, pH 4.7, 10 mM MgCl_2 at 25°C . 10-ml fractions were treated with 0.1 volume of 55% trichloroacetic acid in the presence of 0.5 mg carrier tRNA. The precipitate was filtered on to a glass fibre disk and radioactivity measured in a liquid scintillation photometer. This experiment was repeated twice after reversing the labelling. Absorbance was measured at 260 nm (---). *b*, Similar experiments with tRNA extracted on the eighth day of the fifth instar: ($\times$) PSG tRNA acylated with ^3H -serine; ($\blacksquare$) MSG tRNA acylated with ^{14}C -serine.

species among the eukaryotic tRNA^{Ser} family able to decode UCU, UCC and, with less efficiency, UCA; a minor tRNA^{Ser}_{2c} species is able to recognize the rare UCG codon^{15,16}. The tRNA^{Ser}_{2a} species, which accumulates at a higher level in both silk gland parts than in other non-silk producing tissues (see the carcass in Fig. 3c), might be able to decode specifically the UCA codon—the major serine codon found in fibroin mRNA¹⁷.

A side conclusion can be drawn from these results, based on differential accumulation of specific iso-tRNA^{Ser} species related to the developmental stage of a tissue. The quantitative adaptation of tRNA species to codon frequency demonstrated for a specific and typical mRNA—fibroin or globin¹⁶—leads us to

suggest that the codon usage for serine in the sericin message is somewhat different from that found in fibroin mRNA. The high level of tRNA^{Ser}₁ in the MSG can be easily explained if we state that sericin mRNA carries AGU and/or AGC codons in addition to the UCA codon.

The specific requirement of the iso-tRNA^{Ser} family in decoding different mRNAs in two distinct silk gland parts remains to be understood. We have studied tRNA synthesis using *in vivo* short pulse-labellings of tRNA throughout the last larval instar and then analysed the tRNA species on electrophoretic maps. Synthesis rates of tRNA are not uniform: rapid changes occur, which are specific for each tRNA species and for each silk gland

Fig. 2 Identification of tRNA^{Ser} species from the MSG (eighth day from the fifth instar) fractionated on a BD-cellulose column and analysed by two-dimensional polyacrylamide gel electrophoresis. The first dimension was carried out on 10% acrylamide–bisacrylamide (19:1), 7 M urea, Tris-borate buffer 0.089 M, pH 8.3, and run from right to left for 25 h at 12 V cm^{-1} in the cold. The second dimension was done on 20% acrylamide, 4 M urea in the same buffer and run from top to bottom for 48 h at 13 V cm^{-1} . Gels were stained in 0.2% (w/v) methylene blue solution in 2% sodium acetate buffer, pH 5.0, and destained in running water^{13,14}. *a*, tRNA^{Ser}₂ species from the second peak of the BD-cellulose column (fractions 90–150 from Fig. 1b). *b*, tRNA^{Ser}₁ species from the first peak (fractions 45–80). *c*, tRNA^{Ser}₁ and tRNA^{Ser}₂ species previously purified from a BD-cellulose column carried out in the absence of Mg^{2+} . *d*, tRNA^{Ser}₁ and tRNA^{Ser}₂ co-electrophoresed with 0.5 A₂₆₀ of total PSG tRNA.

part. It has been shown, for example, that $\text{tRNA}_{1\text{Gly}}$, $\text{tRNA}_{2\text{Gly}}$ and $\text{tRNA}_{2\text{Ala}}$ are the most highly labelled species at all times in the posterior part. Their absolute synthesis rates are at a maximum on days 3 and 4, that is, at the end of the growth phase and the beginning of fibroin secretion. In the middle part however, tRNA_{Asp} , $\text{tRNA}_{1\text{Gly}}$, $\text{tRNA}_{1\text{Ser}}$ and $\text{tRNA}_{2\text{aSer}}$ species have high absolute synthesis rates with a maximum shifted in time, whereas other tRNA species are synthesized at lower rates.

A comparison of biosynthetic rates for the iso- tRNA_{Ser} family is of particular interest. Figure 4 shows that during the fifth instar changes in the relative synthesis rates for $\text{tRNA}_{1\text{Ser}}$ and $\text{tRNA}_{2\text{aSer}}$ occur in the two silk gland parts—these changes differ between the two parts. In the PSG, there is an increase in $\text{tRNA}_{2\text{aSer}}$ synthesis with respect to $\text{tRNA}_{1\text{Ser}}$ species at the start of fibroin production. However, in the MSG, $\text{tRNA}_{1\text{Ser}}$ species is preferentially synthesized although the changes are more progressive. We know that these different patterns are essentially due to the highest synthesis rate of $\text{tRNA}_{2\text{aSer}}$ in the posterior, and $\text{tRNA}_{1\text{Ser}}$ in the middle part. These individual changes explain

Fig. 4 Differential synthesis rates of $\text{tRNA}_{1\text{Ser}}$ and $\text{tRNA}_{2\text{aSer}}$ species in the middle and posterior silk glands of *B. mori* silkworm during the fifth larval instar. Silkworms from days 1 to 8 of the last instar were each injected with 0.5 mCi ^3H -uridine and dissected after 4 h labelling. tRNA from posterior (■) and middle (●) silk glands were subjected to two-dimensional polyacrylamide gel electrophoresis and each tRNA_{Ser} spot quantitated. The ordinate indicates time (h) after the first meal following the last moult.

Fig. 3 Differential accumulation of tRNA_{Ser} species on polyacrylamide gel maps from PSG and MSG of *B. mori* silkworm at the end of the fifth larval instar. Two-dimensional electrophoresis was carried out according to Fig. 2 legend. The figures show only the tRNA_{Ser} area corresponding to the upper right part of a complete tRNA electrophoretic map. a, PSG; b, MSG; c, carcass.

the differential accumulations evident in Fig. 1 and shown more precisely in Fig. 3. They seem to be related to the different mRNA populations being decoded.

Of the three possible levels of regulation—preferential degradation of mature tRNA species, selective processing of precursor tRNA, and differential transcription of tRNA genes—we concentrated on the last possibility. The preferential degradation of non-used mature tRNA species can be ruled out, because we have found similar degradation rates for 13 tRNA species, including tRNA_{Ser} species¹³. A selective processing of precursor tRNA, whose primary transcripts would match tRNA gene distribution, cannot be excluded, although preliminary results from silk glands incubated on day 4 for a short time with ^{32}P indicate an enrichment of pre- tRNA_{Ser} in the middle part compared with the posterior part¹³.

Although there is no direct evidence for a transcriptional control of tRNA gene activity according to the needs of the polysomal compartment, the differential appearance and accumulation observed for each iso- tRNA_{Ser} species favour such a mechanism, the most suitable to account for tRNA adaptation to the mRNA codons being translated.

We thank Dr G. Chavancy, A. Fournier and Ms J. Ramsey for critical reading of the manuscript.

Human erythrocyte membranes exhibit a cooperative calmodulin-dependent Ca^{2+} -ATPase of high calcium sensitivity

Peter Downes & Robert H. Michell

Department of Biochemistry, University of Birmingham,
PO Box 363, Birmingham B15 2TT, UK

It is thought that the ionized Ca^{2+} concentration in the cytosol of healthy erythrocytes is in the range 0.01–0.1 μM (ref. 1) and that this low concentration is maintained by an ATP-driven calmodulin-dependent Ca^{2+} pump in the plasma membrane^{2,3}. The Ca^{2+} -stimulated ATPase which is the enzymatic expression of this pump varies in its calcium sensitivity between different preparations of erythrocyte ghosts, with activation generally occurring in a concentration range between ~1 and 10 μM Ca^{2+} (refs 2–5). This is a higher range of Ca^{2+} concentrations than might be anticipated for activation of a pump that sustains intracellular concentrations of Ca^{2+} below 0.1 μM , and recent reports have suggested activation in some membrane preparations at Ca^{2+} concentrations in the range 0.1–1.0 μM (refs 6, 7). We report here a simple method for preparing human erythrocyte membranes in 2.5 mM HEPES/1 mM EGTA at pH 7.0 (see Fig. 1 legend) in which the activation of the Ca^{2+} -ATPase by Ca^{2+} and intracellular concentrations of calmodulin is highly cooperative and is complete by ~1 μM Ca^{2+} . Unlike other available erythrocyte membrane preparations, the pattern of activation by Ca^{2+} and calmodulin is not complicated by partial resealing of the ghosts during and after isolation. We suggest that this cooperative activation of the Ca^{2+} pump may explain how healthy erythrocytes maintain their normal cytosol Ca^{2+} concentration at a threshold value at or below ~0.1 μM . We also note that several other calmodulin-dependent enzymes display similar cooperative activation kinetics.

We first compared the activation by Ca^{2+} of the calmodulin-dependent ATPase activities of human erythrocyte ghosts that had been prepared in various media, but which were all assayed in conditions of ionic strength and of ATP and Mg^{2+} concentration relatively similar to those in the cell. We observed that membranes isolated in 2.5 mM HEPES/1 mM EGTA at pH 7.0 exhibited the behaviour shown in Fig. 1a: activation occurred at lower Ca^{2+} concentrations than with other ghost preparations, and full activation occurred over a narrow range of Ca^{2+} concentrations. A rise from 10 to 90% of full activity required only a four- to fivefold increase in Ca^{2+} concentration, indicating that Ca^{2+} activated the ATPase in a highly cooperative manner (Hill coefficient 3.0 ± 0.4 , $n = 5$). In the presence of a high concentration of calmodulin, substantial activity was expressed at least down to 0.1 μM (Fig. 1a). As the concentration of calmodulin was reduced, however, the proportion of the total activity expressed at micromolar concentrations of Ca^{2+} fell (Fig. 1a, b). These experimental results are very similar to those reported by Klinger *et al.*⁷ but these authors interpreted their data in terms of classical Michaelis-Menten kinetics and thus, we feel, overlooked the potential importance of their observations.

If these results reflect the pattern of activation of the Ca^{2+} pump in the intact erythrocyte, into which Ca^{2+} leaks only very slowly, the ionized Ca^{2+} concentration within the cell would automatically be maintained below 0.1 μM , that is, at the expected level for a healthy erythrocyte. That this pattern may indeed be the correct one, rather than an experimental artefact, was indicated by comparative experiments (not shown) in which the Ca^{2+} dependence of the Ca^{2+} -ATPase was assessed in several membrane preparations, using both unmodified samples and samples treated with 0.1 mg per ml saponin^{7,8}; the preparations tested were the new HEPES/EGTA ghosts, whole

erythrocytes, ghosts prepared in 20 mM Tris/1 mM EGTA and ghosts prepared in imidazole/histidine/EGTA mixtures⁷. In the absence of saponin, the three latter preparations showed either no ATPase (cells) or activation that was much less sensitive to Ca^{2+} and calmodulin than in the HEPES/EGTA preparation, but when saponin was present (to ensure membrane permeability) they all behaved like the saponin-free HEPES/EGTA ghosts illustrated in Fig. 1. We therefore believe that much of the reported variability in Ca^{2+} and calmodulin sensitivity of previously described ghost preparations arose simply because they were partially (and variably) resealed, so that access of added Ca^{2+} , ATP or calmodulin to the ATPase was restricted.

Fig. 1 Activation of $(\text{Ca}^{2+} + \text{Mg}^{2+})$ ATPase by *a*, Ca^{2+} in the absence (○) or presence of bovine brain calmodulin (▲, 56 nM; ■, 280 nM; ●, 5,600 nM), and *b*, calmodulin in the presence of a maximally stimulating concentration of Ca^{2+} (2 μM). Human blood was obtained from the Regional Blood Transfusion Laboratories within 7 days of collection. Erythrocytes were sedimented and washed three times in 0.15 M NaCl/1.5 mM HEPES, pH 7.2, at 4 °C to remove plasma and leukocytes. Cells were lysed in 10 vol of 2.5 mM HEPES/1 mM EGTA, pH 7.0. The membranes were sedimented at 15,000g for 15 min and then washed five times in the same medium. The isolated membranes were stored in this medium at 4 °C for up to 24 h before use. $(\text{Ca}^{2+} + \text{Mg}^{2+})$ ATPase activity was assayed for 30 min at 30 °C in 1 ml of 30 mM HEPES, 30 mM KCl, 80 mM NaCl, 4 mM MgCl_2 , 3 mM ATP, 0.1 mM ouabain, 1 mM EGTA, to which various concentrations of Ca^{2+} were added before adjustment of the pH to 7.0. Calmodulin was isolated from bovine brain¹⁶. Assays contained 0.15–0.2 mg of membrane protein. The ionized Ca^{2+} concentrations were calculated using $k_{\text{Ca}^{2+}\text{-EGTA}}$ of 11.0, as recommended by Owen¹⁷. Reactions were stopped by addition of cold trichloroacetic acid (final concentration 10% w/v) and P_i in the acid-soluble fraction measured¹⁸. Ca^{2+} -ATPase activity was calculated as total ATPase activity minus the activity expressed in the presence of 1 mM EGTA without added Ca^{2+} . The results shown in *a* and *b* are each taken from duplicate incubations in a single experiment, and are typical of results obtained in several experiments of fundamentally similar design. Results of the type shown were consistently obtained in many preparations of ghosts isolated in 2.5 mM HEPES, 1 mM EGTA, pH 7.0, but not in ghosts isolated in various other conditions.

Both we (Fig. 1) and others (for example, ref. 7) have noted that erythrocyte Ca^{2+} -ATPase can express its full activity at concentrations of calmodulin far lower than those present in the cell ($\sim 5 \mu\text{M}$)^{2,7}. Our results (closed symbols in Fig. 1a) and those of Klinger *et al.*⁷ also demonstrate that the calmodulin-dependent activation of the ATPase by Ca^{2+} retains its cooperativity at reduced calmodulin concentrations. However, as the calmodulin concentration is reduced, the apparent affinity for Ca^{2+} declines, suggesting that a function of the high, apparently 'excessive', calmodulin concentration that prevails within cells may be to maximize the sensitivity to Ca^{2+} of an already sensitive Ca^{2+} pump. Further studies using concentrations of Ca^{2+} and/or calmodulin that were inadequate for full activation gave complex results (not shown) that seem to rule out any explanation of activation involving simply the generation of a certain concentration of a particular Ca^{2+} -calmodulin complex as suggested by Cheung⁹; the relationship of these results to the mechanism of cooperative activation will be considered elsewhere.

At $\sim 1.0 \mu\text{M}$ Ca^{2+} , at which full activation of the ATPase was seen in the presence of calmodulin, the 'basal' (that is, calmodulin-independent) Ca^{2+} -ATPase activity of these ghosts was no more than 5% of their maximum activity, but this could be raised, in a relatively non-cooperative manner (open symbols in Fig. 1a), to $\sim 20\%$ of maximum activity at a Ca^{2+} concentration of $\sim 100 \mu\text{M}$. This activity persisted through extensive and varied washing procedures, as did a residual complement of $62 \pm 15 \text{ ng}$ ($n = 3$) of membrane-associated calmodulin per mg of membrane protein (as assayed by the activation of skeletal muscle myosin light chain kinase by heat-denatured erythrocyte ghosts; H. Dolbear and P.D., unpublished results). It therefore seems that soluble calmodulin must be available if the activation of the ATPase by Ca^{2+} is to show its normal cooperativity, but it remains possible that control by Ca^{2+} of the lower-affinity, 'calmodulin-independent' basal activity may still be mediated, in a different manner, by residual calmodulin that is tightly bound in the membrane preparations, as has been suggested previously^{7,10}. If this is correct, this residual calmodulin might be as tightly bound to the membrane ATPase as the calmodulin that is bound into the subunit structure of phosphorylase kinase.

Recent work has suggested that some Ca^{2+} -mobilizing hormones and neurotransmitters evoke intracellular responses by causing relatively small (for example, fivefold) changes in the cytosolic ionized Ca^{2+} concentration (for example, ref. 11). Such small changes in Ca^{2+} concentration should therefore be able to control the key intracellular enzymes responsible for these responses. At least two calmodulin-dependent Ca^{2+} -activated enzymes other than the Ca^{2+} -ATPase (myosin light chain kinase^{12,13} and cyclic nucleotide phosphodiesterase¹⁴) show highly cooperative activation by low concentrations of Ca^{2+} . Recent data suggest that the same may also apply to glycogen phosphorylase kinase when activated through its endogenous calmodulin subunit but not when activated by exogenous troponin I; this cooperativity was not, however, noted in the original paper¹⁵. It seems possible that such cooperativity may be an essential and general characteristic for the functioning of many enzymes that must respond to small changes in cytosol Ca^{2+} concentration. It will be interesting to determine whether the same type of mechanism underlies the cooperative activation by Ca^{2+} of all these calmodulin-dependent enzymes.

We thank the MRC for the award of a research studentship to P.D.

Occluded bound calcium on the phosphorylated sarcoplasmic transport ATPase

H. Takisawa & M. Makinose

Max-Planck-Institut für medizinische Forschung, Heidelberg, Abteilung Physiologie, 6900 Heidelberg, Jahnstrasse 29, FRG

The Ca^{2+} + Mg^{2+} -activated ATPase of the sarcoplasmic reticulum is responsible for the active Ca^{2+} transport of this membrane system¹, the key feature of which is the formation of an energy-rich phosphorylated transport enzyme (EP) and its conversion². To understand the Ca^{2+} -transport mechanism, it is essential to clarify the behaviour of this intermediate in relation to such ligands as ATP, ADP, Mg^{2+} and, particularly, Ca^{2+} . Recent kinetic studies on the phosphate turnover of this system suggested a relatively slow rate of Ca^{2+} dissociation from the phosphorylated enzyme^{3,4}, which possibly indicated Ca^{2+} binding in some occluded form with the intermediate. Here we report direct measurements of the binding and release of Ca^{2+} during phosphorylation of the sarcoplasmic transport enzyme. The results indicate an occlusion of the Ca^{2+} binding, accompanying an initial configurational change of the enzyme induced by the energy-rich phosphoryl transfer.

Figure 1 shows Scatchard plots of Ca^{2+} binding by the vesicular and solubilized sarcoplasmic transport ATPase in the absence of ATP. No essential difference could be observed between assays using 1 and 5 mM MgCl_2 . The curves for both preparations show a break. In the case of vesicular ATPase, the calcium affinities of the preparation, calculated from the slopes of the curves, were $k_{\text{dis}} \geq 1 \mu\text{M}$ and $\approx 10 \mu\text{M}$, which suggests negatively cooperating sites for Ca^{2+} binding^{5,6}. The maximal capacity for Ca^{2+} binding, obtained by extrapolation of the curves in Fig. 1 to the ordinate intercept, corresponds to 2.2-2.3 mol Ca^{2+} per mol of the ATPase phosphorylatable site in the vesicular preparation. Numerous kinetic analyses of the transient and/or steady state activity of the native or the partially purified vesicular sarcoplasmic ATPase have shown that one molecule of the transport ATPase is activated by the binding of two Ca^{2+} (ref. 7). The maximal Ca^{2+} binding capacity obtained from Fig. 1 includes, therefore, 0.2-0.3 mol of Ca^{2+} binding capacity per mol phosphorylatable site in excess. This could be due to the nonspecific Ca^{2+} binding capability of the preparation, for example, due to contamination of the Ca^{2+} -binding protein or of denatured ATPase protein.

All the ATPase preparations formed, with ATP, a maximum of 4-5 nmol phosphoenzyme per mg protein. Based on a molecular weight of 115,000 for the sarcoplasmic ATPase⁸, this indicates that about half of the vesicular or solubilized ATPase preparations consist of enzymatically inert proteins—that is, mainly denatured ATPase protein.

However, the solubilized ATPase protein shows a maximal Ca^{2+} binding capacity of ~ 1.4 mol per mol of phosphorylatable site. As both the ATPase preparations show the same specific activity, it is reasonable to assume that they both contain the same amount of inert protein. Thus, the subtraction of nonspecific Ca^{2+} binding capacity found in the vesicular preparation gave a maximal Ca^{2+} specific binding capacity of the solubilized ATPase which was almost half that of the former preparation. A break in the Scatchard plots of solubilized

Fig. 1 Scatchard plots of Ca^{2+} binding by the vesicular and solubilized Ca^{2+} -transport ATPase. Binding of Ca^{2+} to the ATPase was determined by the flow-dialysis method of Colowick and Womack¹⁰ in solutions containing 0.4 M KCl, 0.3 M sucrose, 1 (○, ●) or 5 mM (□, ■) MgCl_2 and 50 mM Tris-TES (tri-methylamino ethanesulphonic acid), pH 8, at 5°C. The concentration of the enzymes was adjusted to 3 mg ml⁻¹ and, in the case of solubilized ATPase (●, ■), 3.5 mg ml⁻¹ deoxycholate (DOC) was included in the assay. Vesicular ATPase (partially purified sarcoplasmic reticulum vesicles: ○, □) was prepared by the method of Meissner *et al.*¹¹. To obtain the solubilized ATPase, 3.5 mg ml⁻¹ of the sarcoplasmic protein was solubilized with DOC (3.5 mg ml⁻¹) in the presence of 0.4 M KCl, 0.3 M sucrose and 50 mM Tris-TES, pH 8, at 5°C¹². After pelleting of the non-solubilized proteins (105,000g for 50 min), the supernatant contained ~3 mg of protein and 3.5 mg of DOC per ml. About 6 nmol Ca^{2+} per mg protein (obtained by atomic absorption spectrometry, Perkin-Elmer Model 4000) constituted Ca^{2+} contamination in both enzyme preparations. The measurement of Ca^{2+} binding was started by the addition of 4 nmol (3.2 μCi) ⁴⁵Ca to 1 ml of the enzyme solution. The Ca^{2+} concentration was increased stepwise up to 2 mM by the addition of 'cold' CaCl_2 . The ordinate is the amount of Ca^{2+} bound per mol of phosphorylatable site of the preparation used. The maximum amount of phosphoprotein was estimated in an assay containing 3 mM CaCl_2 , 1 mM MgCl_2 and 100 μM ATP, as 4–5 nmol EP per mg protein for both the vesicular and solubilized ATPase.

ATPase (Fig. 1) is presumably due to the nonspecific bound Ca^{2+} capacity. Apparently, the solubilization reduces the affinity of one of the two sites of the enzyme for Ca^{2+} .

This raises the question of whether the solubilized sarcoplasmic ATPase requires one or two Ca^{2+} for its activation. Because the rate of the EP formation of the solubilized ATPase is much slower than that of the vesicular ATPase (data not shown), the time course of EP formation can be easily followed. Figure 2 shows the change of EP level, extra Ca^{2+} binding and P_i liberation during transient EP formation. It is evident that the extra binding of Ca^{2+} was accompanied by EP formation and the amount of additional Ca^{2+} bound to the ATPase was almost equal to the amount of EP formed. No correlation was found between the time course of additional Ca^{2+} binding and P_i liberation. Apparently, two Ca^{2+} are also required for the activation of the solubilized sarcoplasmic ATPase. The reaction steps for the activation of the solubilized ATPase can thus be formulated:

Table 1 Retention of bound calcium on the phosphorylated sarcoplasmic transport enzyme

ATPase preparation	Addition	Effluent contents		
		Calcium* (nmol)	Phosphorylatable site (nmol)	Mol bound Ca^{2+} per mol phosphorylatable site
Vesicular	None	0.180 ± 0.005	0.244 ± 0.004	0.739 ± 0.010
	None	0.099 ± 0.005	0.306 ± 0.004	0.324 ± 0.015
Solubilized	ATP (100 μM)	0.371 ± 0.011	0.259 ± 0.019	1.437 ± 0.076
	AMPPCP (200 μM)	0.091 ± 0.007	0.281 ± 0.007	0.322 ± 0.024

A small Sephadex G-50 column (4.7 × 57 mm) prepared according to Penefsky⁹ was equilibrated with a solution containing 0.4 M KCl, 0.3 M sucrose and 50 mM Tris-TES, pH 8. The enzymes (3 mg protein ml⁻¹), were incubated with ⁴⁵CaCl₂ (1 mM) in the presence or absence of ATP (100 μM) or AMPPCP (200 μM) in a solution containing 0.4 M KCl, 0.3 M sucrose, 80 μM MgCl_2 and 50 mM Tris-TES, pH 8 at 0°C for 2 min. An aliquot of the assay (50 μl) was transferred to the top of the column and centrifuged immediately (150g for 2 min at 5°C) and the effluent calcium and protein content were measured. The enzyme preparations showed the maximal phosphorylatable site number of 5.1 nmol per mg protein using the method described in Fig. 1 legend, with no significant difference between the vesicular and the solubilized enzyme. Values are the means of four determinations ± s.e.m.

* The calcium content of the effluent in the control experiment containing no protein was <0.002 nmol.

The solubilizing procedure affects the ATPase by reducing its affinity for the second Ca^{2+} (K_2), so that, at the concentration of Ca^{2+} which is usually sufficient to activate the transport enzyme (for example, 90 μM as in Fig. 2), one solubilized ATPase molecule binds about one Ca^{2+} . If ATP is added, step 3 of the reaction is activated and the enzyme is accumulated in the form of E*PCa_2 , which retains two Ca^{2+} per molecule. The binding state of the Ca^{2+} with this enzyme species should be very different from that of the unphosphorylated enzyme species.

In the experiments shown in Table 1, the ATPase preparations, after incubation in appropriate conditions, were centrifuged through a small Sephadex column to rapidly remove the incubation medium (centrifuge column method⁹). As the enzyme is exposed to the ligand free-solution in the column

Fig. 2 Extra Ca^{2+} binding to the solubilized sarcoplasmic ATPase during EP formation. The reaction was started by adding 50 μM [γ -³²P]ATP to the assay containing 3 mg ml⁻¹ solubilized ATPase protein, 3.5 mg ml⁻¹ DOC, 0.4 M KCl, 0.3 M sucrose, 90 μM CaCl_2 , 80 μM MgCl_2 and 50 mM Tris-TES pH 8.0, at 5°C and terminated after the appropriate time by addition of 4% trichloroacetic acid containing 0.1 mM ATP and 0.2 mM P_i . EP formation and P_i liberation were measured as described elsewhere^{13,14}. Change in the concentration of Ca^{2+} was measured in the same assay containing 100 μM Murexide¹⁵. The reaction was started with quick addition (within 1 s) of 50 μM cold ATP and the absorbance change of the dye at 507/540 nm was registered on a Aminco DW-2 spectrophotometer. The addition of ATP caused an immediate change in absorbance corresponding to the decrease in Ca^{2+} concentration of ~2 μM due to formation of Ca -ATP complex. This deviation was subtracted from the original trace.

during the separation time, the bound ligands, particularly the rapidly exchangeable ligands, are partially removed from the enzyme protein. When the vesicular ATPase was preincubated in solution containing 1 mM Ca^{2+} , 0.74 mol of Ca^{2+} was bound per mol active enzyme after centrifugation instead of the expected 2 mol. In the case of solubilized ATPase, 0.32 mol of Ca^{2+} was bound per mol of ATPase instead of the expected 1 mol. Apparently, about two thirds of the rapidly exchangeable bound Ca^{2+} is removed from the ATPase protein in this procedure. When the solubilized ATPase was incubated with 100 μM ATP and 1 mM Ca^{2+} , 1.44 mol of Ca^{2+} were bound per mol active enzyme in the effluent. In a parallel assay with 'hot' ATP and 'cold' Ca^{2+} , in the effluent, 32% of the phosphorylatable sites of the enzyme were unphosphorylated and 68% were phosphorylated. Therefore, 1 mol of the active ATPase in these effluents retains 0.1 mol (32% of 0.32 mol) Ca^{2+} , which represents the unphosphorylated state and the remaining 1.34

mol Ca^{2+} represents the phosphorylated state (68% of 1 mol). Thus, even after column centrifugation, 2 mol of Ca^{2+} are retained by 1 mol phosphorylated enzyme. Addition of 200 μM AMPPCP (non-hydrolysable ATP analogue) had no effect on the Ca^{2+} -binding of the solubilized ATPase.

The condition for EP formation in which bound Ca^{2+} cannot be removed is low Mg^{2+} concentration (80 μM). When the experiment in Fig. 2 was done using 5 mM Mg^{2+} , addition of ATP caused a transient increase in Ca^{2+} concentration in the assay, as observed previously by Ikemoto⁵. A high Mg^{2+} concentration presumably effects the further conversion of the phosphoprotein, resulting in Ca^{2+} liberation and dephosphorylation. The occlusion of the bound calcium on the transport ATPase molecule is coupled with an initial configurational change of the enzyme molecule caused by phosphorylation of the enzyme protein, but not by formation of the substrate-enzyme complex.

Direct observation by NMR of two coexisting conformations of an enzyme–ligand complex in solution

A. Gronenborn, B. Birdsall, E. I. Hyde, G. C. K. Roberts*, J. Feeney & A. S. V. Burgen

Division of Molecular Pharmacology, National Institute for Medical Research, London NW7 1AA, UK

Dihydrofolate reductase is the site of action of the 'anti-folate' drugs, such as methotrexate, pyrimethamine and trimethoprim, which act as competitive inhibitors of the enzyme^{1–3}. These inhibitors bind to the *Lactobacillus casei* enzyme cooperatively with the coenzyme NADP(H), which can increase inhibitor binding by as much as 700-fold⁴. The existence of conformational changes accompanying ligand binding and involved in inhibitor–coenzyme cooperativity has been inferred from NMR experiments^{4–9}. It seems likely that these conformational changes are important in determining the specificity of the enzyme for its ligands^{4,10,11}. We now report the direct observation by NMR of two distinct conformations of the enzyme–trimethoprim–NADP⁺ ternary complex in solution.

Figure 1 compares the histidine C¹–H resonances of this complex with those of the enzyme–methotrexate–NADP⁺ complex. The resonances of all seven histidine residues¹², labelled A–G, are clearly resolved in these conditions. Their positions are closely similar in the two complexes (for a detailed comparison, see ref. 13), with the exception of resonance F. This has been assigned to His 28 (ref. 14), which is seen in the crystal structure¹⁵ of the enzyme–methotrexate–NADPH complex to interact with the γ -carboxyl of the glutamate moiety of methotrexate. As there is no corresponding group in trimethoprim, the pK of His 28 is ~ 1.3 units lower in complexes with trimethoprim than in those with methotrexate^{13,16}.

The most striking difference between the two spectra in Fig. 1, however, is that in the spectrum of the trimethoprim complex resonances E (tentatively assigned to His 18 (refs 13, 14)) and F are split into two peaks, each of intensity corresponding to approximately half a proton (compare resonances A, B and D).

The separation between these two components of resonances E and F, measured in hertz, is directly proportional to magnetic field strength and therefore represents a chemical shift difference. The spectra thus show that the enzyme–trimethoprim–NADP⁺ complex exists in two forms which differ in the environments of two histidine residues, His 28 and, probably, His 18. The approximately equal intensity of the two components of the histidine resonances indicates that these two forms are present in approximately equal amounts.

If these two forms interconvert with one another, they must represent different conformational states of the complex. The observations of two distinct signals separated by only ~ 15 Hz (at 270 MHz and 5 °C) implies that such an interconversion must be slow. We have demonstrated that interconversion occurs and measured its rate by determining the temperature dependence of the line shape of histidine resonances E and F over the range 0–50 °C at both 270 and 470 MHz. The results at 470 MHz are shown in Fig. 2.

As the temperature is increased, the two components of each histidine resonance broaden, and then coalesce into a single line which sharpens as the temperature is increased further. This behaviour is that expected for a progressively increasing rate of interconversion between the two states represented by the two components of the absorption band. (The progressive downfield shift of the resonances with increasing temperature is due to the temperature dependence of the pK values of the histidine residues.) These changes in line shape, and particularly the broadening of the resonances with increasing temperature at low temperature, cannot be accounted for by any model in which there is no interconversion between the two states, thus eliminating the possibility that they correspond to two hitherto undetected isoenzymes of the kind observed in *Escherichia coli* RT500 (ref. 17).

The observed line shapes can be satisfactorily simulated, as indicated in Fig. 2, on the basis of a model involving interconversion between just two states of the protein. These simulations allow us to estimate the rate of interconversion at each temperature, taking the chemical shift difference between the two states as that measured at 5 °C (0.044 p.p.m. for resonance F, 0.063 p.p.m. for resonance E). The estimated rates range from 2 s^{–1} at 26 °C to 80 s^{–1} at 51 °C. Four independent estimates of the rate can be made at each temperature from simulation of resonance E and resonance F each at 270 and 470 MHz. These four estimates always agreed within $\pm 15\%$,

* To whom correspondence should be addressed.

indicating that the two-state model of the interconversion process is adequate. The fact that the two components of resonance F coalesce at a lower temperature than those of resonance E can be simply explained by the smaller chemical shift difference between the two states in the former case. The activation parameters for the interconversion, calculated from the temperature dependence of the estimated rate constants, are: $\Delta H^\ddagger = 25(\pm 3)$ kcal mol⁻¹, $\Delta S^\ddagger = 29(\pm 8)$ cal K⁻¹ mol⁻¹. There is no detectable change in the relative proportions of the two states over the temperature range studied.

Note that the splitting of the two histidine resonances is not observed in either the enzyme-trimethoprim or the enzyme-NADP⁺ binary complexes. The observation of two coexisting conformations of the ternary complex but not of either binary complex is clear evidence for the existence of conformational changes specific to the ternary complex. These may be involved in the observed cooperativity in binding between NADP⁺ and trimethoprim.

Examination of the three-dimensional structure of the enzyme-methotrexate-NADPH complex¹⁵ shows that the backbone carbonyl group of His 18 forms a hydrogen bond to the 3'-hydroxyl of the nicotinamide ribose of the bound coenzyme. His 28, on the other hand, is farther both from the bound coenzyme and from trimethoprim (bound in the conformation deduced from ¹H NMR data¹⁸). We have recently shown¹⁹ that the interaction of the nicotinamide ring of the coenzyme with the enzyme and the conformation of the bound coenzyme both differ between the two conformations of the ternary complex. The two environments of His 18 may thus reflect the two modes of interaction of the coenzyme. The effect on His 28, however, indicates that the conformational differences between the two states of the complex extend beyond the residues in direct contact with the bound ligands.

Fig. 1 Histidine C^{ε1}-proton resonance region of the ¹H NMR spectrum of *L. casei* dihydrofolate reductase in its complexes with methotrexate (MTX) and NADP⁺ (top) or trimethoprim (TMP) and NADP⁺ (bottom). The resonances of the seven histidine residues are labelled A–G. The spectra were obtained at 270 MHz using a Bruker WH270 spectrometer in the Fourier transform mode. The samples consisted of ~1 mM enzyme in 0.35 ml² H₂O containing 50 mM potassium phosphate, pH (meter reading) 6.5, 500 mM KCl. Approximately 2,000 transients obtained using quadrature detection, with 8,192 data points for a spectral width of 4.2 kHz, were averaged for each spectrum. Before Fourier transformation, the free induction decay was multiplied by an exponential equivalent to a line broadening of 2 Hz. Chemical shifts are expressed relative to internal (1 mM) dioxan (3.71 p.p.m. downfield from dimethylsilapentane-5-sulphonate).

Fig. 2 The histidine C^{ε1}-proton resonances E (on the right) and F of the dihydrofolate reductase-trimethoprim-NADP⁺ complex as a function of temperature. The line shapes simulated using the equation for a two-site exchange process, with the chemical shift difference measured at 5 °C and the rate constants shown (chosen for the best visual fit to the experimental spectra), are shown at either side. The experimental spectra were obtained as described in Fig. 1 legend, but using the 470-MHz spectrometer of the Oxford Enzyme Group.

The coexistence of two or more conformational states of an enzyme complex has often been postulated, or inferred from indirect evidence, in this and other systems. In the present case, however, we are able to observe two coexisting conformational states directly in solution, measure their rate of interconversion and begin to characterize the structural differences between them.

We thank Gill Ostler and John McCormick for technical assistance and the Oxford Enzyme Group, particularly Iain Campbell and Peter Stiles, for the use of their 470-MHz NMR spectrometer. E.I.H. is supported by a MRC Research studentship.

BOOK REVIEWS

Computers born of crisis

S.J. Goldsack

A History of Computing in the Twentieth Century. Edited by N. Metropolis *et al.* Pp.688. (Academic: 1980.) \$29.50, £16.60.
Early British Computers. By S. Lavington. Pp.139. (Manchester University Press: 1980.) Hbk £7.95; pbk £3.95.

SEPARATELY, these books would both be well worth reading by anyone with an interest in the origins of computing as we know it today. Together I found them fascinating. Both volumes claim to be of interest to the non-specialist reader, as well as to the technically aware. I would judge that this claim is reasonably justified; however, I think that an understanding of the technical background would certainly help.

The book by Metropolis *et al.* is the more important. In June 1976, a conference on the history of computing was held in Los Alamos. Its purpose was to bring together as many as possible of the pioneers who created the modern computer, to tell the story of their work. The timing was none too early; already important figures such as J. von Neumann, A. Turing and F.C. Williams, whose presence would have added greatly to the proceedings, had died. Their places were taken by colleagues who had shared in their work. Speakers described the early work on the design and use of computers in America, England, Germany, Russia and Japan. The book is essentially the written record of that conference.

Many of the basic concepts involved in computing were understood before the outbreak of war in 1939. However, the urgent need for tools of computation in connection with war work, and the great technical advances in electronics which were brought about by the efforts in radar and other fields, produced circumstances in which the construction of electronic computers could prosper.

It is commonplace to recognize how the threat of war in the 1930s, and the war effort that followed, fostered technical advances in many fields. The participants in these efforts experienced a uniquely exciting period in their lives. The intrinsic scientific interest of the work in which they were involved, the urgency with which the research was pursued, and, perhaps for the first time, a political commitment by the governments involved to ensure that the resources required were as far as possible made available, combined to create an atmosphere which had not before been

M.J. Lanigan and Tom Kilburn with a section of the transistorized MUSE computer in 1959. This prototype was a forerunner of the Ferranti ATLAS, inaugurated by Sir John Cockcroft in 1962, which incorporated several new concepts in computer design.

encountered. After 1945, those involved returned to the universities, or to newly established research centres, fired with enthusiasm to continue the work which they had started in the urgent circumstances of international crisis. As a student in the immediate post-war period, it was impossible not to sense the enthusiasm which our teachers brought to their work.

The authors of this book were not primarily writing memoirs of their experiences; yet the effect of the collection of accounts by all the parties participating in work relating to electronic computers about how progress was achieved in the different centres, and the interrelation between them, creates a strong impression of the vitality of the period.

It would not be realistic to single out particular papers as worthy of special notice, as the interest of the book lies in the way in which the contributions of the various authors combine to create a complete picture. Inevitably, however, there is special interest in those papers describing work done in conditions of secrecy during the war, and of which these accounts are among the first publicly available. They include, for example, the description of the Colossus machines, used to decipher German codes by the British Secret Service — oddly, this work was sponsored by the Foreign Office! I personally learned much of which I was

ignorant, or only dimly aware. I had failed to appreciate, for example, how widely the Williams storage tube was used on both sides of the Atlantic for a period before the invention of magnetic core stores.

The volume addresses the history of computing. Though hardware has pride of place, the developments in programming and programming languages are included. It would be impossible to appreciate the development of computer architecture, without understanding the need for better facilities for the programmer.

The date chosen, tacitly, to determine the end of history and the start of the modern era was rather arbitrary. Historical computers, it seems, used valves: transistors belong to the modern era. The computers of the second generation, which saw the development of operating systems and complex software, were not covered. Perhaps a future conference should address the history of programming and software; it is doubtful, however, whether it would reach the same level of interest for the general reader as is achieved in this book.

It is not surprising, perhaps, that Lavington's volume should appear at about the same time as the other. Lavington presented the work of the Manchester group under F.C. Williams at Los Alamos, and, no doubt, his book was inspired in part by the research involved in

preparing his contribution to the larger work. Though it has less scope and significance, it does include an account of the ATLAS Computer which was largely developed at Manchester and which introduced the concept of virtual storage in the early 1960s.

Lavington's early chapters, which attempt to give in a few pages a technical account of the early developments, are rather shaky. However, the style quickly settles down to an interesting description which reinforces and extends the material of the larger book. □

S.J. Goldsack is Professor in the Department of Computing at Imperial College, University of London.

Charles Babbage, 1792–1871, who devised the basic principles of modern computers.

Alan Turing, a leading figure in the early days of computer design. He died in 1954.

Computing and optics in context

P.W. Hawkes

The Computer in Optical Research. Edited by B.R. Frieden. Pp.371. (Springer-Verlag: 1980.) DM 98, \$57.90.

SOME topics seem so naturally adapted to a multi-author series such as this that when the corresponding volume does appear it is hard to realize that it has no rivals. Frieden's collection is a good example: most of the material is available elsewhere, scattered throughout the literature though not necessarily that of optics, but how very much more useful and usable it becomes, gathered into a single volume, put in context and with a recognizable pattern imposed on it.

Five subject-areas are explored. First, R. Barakat describes the calculation of the various types of integrals that arise in diffraction theory; his aim is to draw attention to the methods that have been developed by numerical analysts, with which specialists in other fields are all too often unfamiliar. This is followed by a long and extremely important chapter by Frieden on probability and statistics. This contains a formal but highly readable account of those aspects of the subjects that Frieden believes to be valuable in optics. After arguing persuasively that such methods are likely to become all-pervasive in this field, he regrets that progress is slow since "most optical workers simply do not know the methods" even though "first applications in optics have been highly successful". He claims, quite justifiably, that his chapter is the "first exposition on probability and statistics written specifically from the

optical perspective and for the optical community".

The remainder of the book is less revolutionary though of considerable interest. A.K. Rigler and R.J. Pegis give a knowledgeable account of optimization methods, L. Mertz examines computers and optical astronomy and W.J. Dallas surveys the computer generation of holograms. Every chapter is filled with practical information, illustrated with numerous examples, and it is clear either that Frieden has submitted the chapters to thorough editing to ensure uniformity of tone or that he chose his contributors very skilfully. Furthermore, he has written an introductory chapter that adds substantially to the usefulness and readability of the remainder. In this, he writes what amounts to a long essay-review of the book, explaining informally how the individual chapters are organized and giving his own opinions of the place of particular approaches in optics. In addition he draws attention, sometimes anecdotally, to other topics that could have been included, or are at too preliminary a stage of development to appear in the main text; Fienup's modified version of the Gerchberg-Saxton algorithm is an example of this.

It is not often that the multi-author formula is entirely satisfactory but here it works to perfection. The best way of recommending this wholly excellent book is to say that I cannot understand how we have been managing without it. □

P.W. Hawkes is Maître de Recherches at the Laboratoire d'Optique Electronique du CNRS, Toulouse.

The double layer in electrochemistry

Andrew Hamnett

The Double Layer. Comprehensive Treatise on Electrochemistry, Vol.1. Edited by J. O'M. Bockris, B.E. Conway and E. Yeager. Pp.453. (Plenum: 1980.) \$49.50, £31.19.

THE Plenum Press have published a remarkable series of books on electrochemistry in recent years, and the *Comprehensive Treatise on Electrochemistry* is their latest and most ambitious venture. This first volume contains nine articles on aspects of the double layer written by such well-known electrochemists as Parsons, Bockris, Frumkin and Damaskin. Inevitably, these articles make rather varied intellectual demands on the reader, from the considerable in the case of Parsons' introductory article on thermodynamics, to the pedagogically straightforward

account by Reeves of the double layer without specific adsorption.

Parsons' account of the Gibbs adsorption isotherm is rightly given the task of introducing this volume. It is an essay of considerable erudition, though the development of the basic equations is very abstract. Some didactic edge is therefore lost in the early part of the essay and only recovered when the author considers some specific examples of electrode configuration.

The two articles by Reeves and by Habib and Bockris constitute the central part of the book. They are both clear and well written, though I would have preferred a more thorough and detailed account of the recent developments in double-layer theory described in Reeves' article. The essay by Bockris and Habib on specific ionic adsorption is a thorough account of a

highly controversial area; indeed, some of the flavour of this controversy is evident in the article, lending it at times an almost polemical tone. Equally clear is the discussion by Damaskin and Kazarimov on the adsorption of organic molecules onto electrodes; from the pedagogical point of view, this is the most successful article in the book.

Frumkin and co-authors present a detailed account of the concept of potential of zero charge. This topic has attracted several recent reviews and a book (by Frumkin); the present article is in fact a reprise of that book and will be welcomed therefore in the West. The importance of the concept of pzc is amply illustrated in the

present review and my only criticism is that there remain some problems in notation, both between this article and others in the volume, and indeed between text and figure captions.

The articles by Pleskov, Boguslavsky and Hunter are devoted to various aspects of the non-metal/electrolyte interface. Pleskov's essay reviews the double-layer on classical semiconductors and is an able summary of the famous book by Myamlin and Pleskov (*Electrochemistry of Semiconductors*; Plenum, 1967), but I was disappointed to find so few references to work of the past decade, especially given the explosion of interest that has occurred in this field. Boguslavsky has provided a

welcome if rather tentative account of the insulator/electrolyte interface and Hunter a brief but most useful description of colloids.

The present volume contains some essays of great value; in others the development is rather eclectic and the overall result is somewhat uneven. Nevertheless, the first volume of this series will undoubtedly become a standard work. Nothing quite so detailed has been attempted before in electrochemistry, and firmer editorial control should ensure that subsequent volumes will more than fulfil its promise. □

Andrew Hamnett is University Lecturer in Inorganic Chemistry and Fellow of St Catherine's College, Oxford.

Population genetics with age — not forgetting the genes

Michael Bulmer

Evolution in Age-Structured Populations. By Brian Charlesworth. Pp.300. (Cambridge University Press: 1980.) Hbk £18, \$44.50; pbk £5.95, \$13.50.

THIS is the first book in a new series called *Cambridge Studies in Mathematical Biology*, the aim of which is that "each book will be self-contained, covering necessary background theory, but without allowing the mathematical details to obscure biological relevance". The book under review admirably fulfils these aims.

The classical theory of population genetics assumes a life-history with discrete, non-overlapping generations in which all individuals in the population at a particular time are the same age. This model is appropriate for annual plants and insects, but not for a large number of species (most vertebrates, for example) with overlapping generations. In the latter situation, the population at a particular time consists of individuals of different ages with fecundities and survival probabilities dependent on their age, and a proper theory of its population genetics should take its age structure into account. In particular, it is clearly impossible to consider how natural selection moulds the way in which fecundity and survival depend on age without considering age structure, so that recent interest in the evolution of life-history strategies has stimulated theoreticians to extend classical population genetics theory to include age-structure as a variable. Brian Charlesworth reviews and summarizes this work, much of which is his own.

Five chapters develop the subject in a logical way. The first introduces the relevant demographic theory, and the next discusses population genetics in age-structured populations without selection (Hardy-Weinberg and linkage equilibrium, and genetic drift in finite populations); of particular value is the

description of the elegant work of Hajnal on the frequencies of consanguineous matings in an isolated population.

Chapters 3 and 4 form the core of the book and describe the effect of selection in an age-structured population. The author remarks that important work on this subject was published by Haldane and Norton in the late 1920s, but that further work was inhibited by the introduction by Fisher of his "Malthusian parameter" method in 1930, which apparently provided a simple and elegant answer to the problem. However, it has been recognized in the past ten years that this method is defective because a particular genotype cannot have a fixed Malthusian parameter when the genotypic composition of the population is changing under selection; there is no short-cut to the methodology introduced by Haldane and Norton.

Finally, Charlesworth discusses the evolution of life-history strategies, that is to say the evolution of senescence and of reproductive patterns. This is the most interesting area of application of the ideas developed in the book; the author's general conclusion is that

although qualitative agreement between theoretical expectation and observed differences in life-histories between and within species is often good, no studies of natural populations have really been capable of demonstrating close quantitative agreement between a real and an optimal life-history.

Few would disagree with this comment.

This is an important book which can be recommended to anyone with an interest in population genetics and evolutionary biology. The argument is presented clearly from first principles; the author does not belong to the hand-waving school of thought which believes that, when the going gets difficult, it is possible to do population genetics without genes. The mathematical level is reasonably straightforward, but it is at times difficult to see the

wood for the trees; a reader might do well to make a rapid first reading before studying the details.

Incidentally, it should be noted that Bernardelli is throughout mis-spelt "Bernadelli"; this is probably a copying error from a secondary source — a classical deletion mutation. □

Michael Bulmer is a Lecturer in Biomathematics at Oxford University.

MICROCOMPUTERS and PHYSIOLOGICAL SIMULATION

James E. Randall, Indiana University
School of Medicine, Bloomington

Foreword by Arthur C. Guxton, University of
Mississippi School of Medicine, Jackson

"Here is where Dr. Randall's book is invaluable:
the background information on microprocessors,
combined with specific examples of biological
data simulated with various hardware and
software configurations, should allow any life-
science experimenter to progress rapidly from
the initial idea to a working simulation model."

BYTE

Contents:

Introduction. Microcomputer Components.
Operating Systems and Programming Languages.
Hardware Enhancements for Simulation. Repre-
sentative Microcomputers. Compartmental
Kinetics: A First Example. The Glucose Tolerance
Test. Cardiovascular System Mechanics. Arterial
Pulse Pressure. Vectorcardiography and the Limb
Leads. Distortion of Waveforms. Axon Action
Potentials. Cardiac Action Potentials. Formatting
Student Exercises. Index.

1980. 250 pp., illus. Paper 06128 \$14.50

Brochure Available from Publisher.

Some worthy publicity for elastin

A. Serafini-Fracassini

Biology and Pathology of Elastic Tissues.
Frontiers of Matrix Biology, Vol.8. Edited
by A.M. Robert and L. Robert. Pp.230.
(S. Karger: 1980.) \$74.25, SwFr.124.

THIS book attempts to expound, for the
benefit of graduate students and profes-
sional investigators, various areas of
scientific research which are contained
within the subject of molecular biology and
pathology of elastin. This is undoubtedly a
topic of considerable importance to bio-
chemical and medical workers, and one
which has attracted a large amount of
research over the past two decades. As
unambiguous interpretations of functional
properties of the protein still prove elusive,
it is of some value to have, brought
together in one volume, a collection of
critical evaluations of some recent
findings. The earlier contributions in the
book deal with structural and con-
formational aspects of the protein, while
the others discuss its implication in the
inflammatory response and in some tissue
disorders. The role of elastases in these
pathological conditions is adequately
outlined. However, in this context, one
would like to have seen included an up-to-
date account of the biosynthesis of elastin,
with particular reference to the nature of
the soluble biosynthetic intermediate and

to the biogenesis of the cross-links. Such a
chapter would have been of great value to
an outsider to the subject in appreciating
the significance of some structural features
of the protein and in understanding the
pathogenesis of specific disorders. Other
aspects which with advantage could have
been covered more fully are the physico-
chemical properties of elastin, and the
thermodynamics of its deformation to
balance Dr Urry's excellent contribution
on synthetic repeat polypeptides.

It is difficult to make a unified
judgement on this collection of papers
because the style of the contributions is so
varied. Some offer an accurate review of
the relevant scientific research, while
others mainly outline the results obtained
in the authors' laboratories, occasionally
with the exclusion of some lines of research
that might have merited discussion. This is
also reflected by the variable number of
references cited at the end of each chapter.

The book is well produced, adequately
illustrated and as a whole very readable.
Elastin has not yet enjoyed its share of the
general escalation in scientific pub-
lications, and I consider this a worthy
collection, one which could be read with
profit in its entirety by non-specialists. □

A. Serafini-Fracassini is Professor of Bio-
chemistry at the University of St Andrews.

Compleat diquat and paraquat

R.J. Hance

The Bipyridinium Herbicides. By L.A.
Summers. Pp.449. (Academic: 1980.) £33,
\$79.50.

ONLY two bipyridinium herbicides, diquat
and paraquat, are in widespread use, so it is
interesting to speculate why they have
stimulated a book of this size when larger
groups of herbicides have not. Perhaps
there are two reasons. The first is the
enthusiasm of Dr Summers for his subject.
The second is that, in comparison with
other herbicides, the peripheral synthetic
chemistry of these compounds is
challenging and their toxicology unusual.
Indeed, these topics occupy almost half the
book. The remainder covers the chemistry
of the respective diquatery salts,
structure-activity relationships, environ-
mental fate, occurrence and analysis of
residues, herbicidal use and modes of
action.

With 2,500 references cited in little over
400 pages the text is hard going in places
but, by intelligent use of tables, the author
has done his best to avoid producing a
catalogue. The only reasonable criticism
that might be made is that not all readers
will follow the logic underlying the
sequence in which subjects are presented.

For instance, the chapters dealing with fate
in biological systems and with residues are
separated from that on toxicology and
environmental effects which in many
respects is closely related. The layout
within chapters also occasionally seems
strange. There is a good example on p.394,
where a paragraph describing the most
effective ways of treating paraquat
poisoning is placed in the middle of a
section rather than at the end where it
would have more impact. However, the
book is sensibly indexed so the reader
should have little difficulty in finding
specific information.

Nowadays, books including a range of
specialist subjects tend to be multi-
authored. For one man to tackle such a task
successfully is an impressive feat of
scholarship and Dr Summers deserves
warm congratulation. His book
undoubtedly will become a standard
reference. It shows, incidentally, that there
remains a place for books of this type
alongside the computer-based information
retrieval systems that seem to threaten their
viability. □

R. J. Hance is leader of the Herbicide Group at
the Agricultural Research Council Weed
Research Organization, Yarnton, near Oxford.

Reagan's non-existent science advisors

Why is the Reagan Administration dragging its feet on the appointment of a Science Advisor in the White House? More than two months have now passed since Dr Frank Press packed his bags and left. From time to time, this or that distinguished person has been mentioned as a possible successor, only to sink beneath the waves of gossip again. The President's budget request dutifully includes provision for a Science Advisor and a small staff, but at the present rate the new fiscal year will have begun before the Administration will be writing cheques against this line item. It is, however, inconceivable that the motive for the delay in appointing a successor to Dr Press is simply parsimony. Even the new stringent budget includes many more extravagances than this modest office. Nor is it likely that the failure to appoint a Science Advisor stems from a lack of qualified candidates. Although some of those mentioned in connection with this office are probably too accustomed to speaking out in public to suit the White House, there can be no enduring shortage of people able to take on the job. Moreover, it is unlikely that President Reagan's White House is fearful that anyone appointed to the post would have to walk in Dr Press's shadow for too long. By common consent, Dr Press did the job superbly, but the new Administration seems not to have been shy of appointing less well known people to other posts previously occupied by relative giants.

The most charitable explanation is that the new Administration has sought to avoid the encumbrance of a Science Advisor while putting together its budget request. And it is easy enough to understand what a nuisance such a person would have been in the past few weeks. The proposal to cancel the United States half of the joint mission, with the European Space Agency, to put a pair of satellites in polar orbits about the Sun would have evoked a string of memoranda explaining that such a course of action might permanently damage the chances of international collaboration on technical projects. Similarly, the Administration may have calculated, the plan to take the National Science Foundation out of science education would certainly have produced a reflex reaction from any Science Advisor anxious to keep his links intact with former colleagues in the wider world. More memoranda would have filtered over from the Old Executive Office. President Reagan's spirits must have sunk quite low at the prospect that a newly appointed Science Advisor, anxious to make his mark alongside the Killians and Wiesners, would have chosen to offer unsolicited and largely unusable (let alone unwelcome) advice about the new Administration's armoury and its lack of policy (so far) on arms control. Why not wait until the summer, when some of the dust will have settled, before inviting such unnecessary problems? On this charitable calculation, the next President's Science Advisor will be tapped on the shoulder some time about midsummer, when his or her plans to spend a vacation at Woods Hole, Aspen or in Europe are too far advanced to be cancelled easily, will take up office in the middle of the next frenzied budget process, and will not start writing awkward memoranda until fiscal 1983.

dominates everybody's thoughts. That is the charitable calculation of the new Administration's most charitable motivation.

Unfortunately, more sombre, even sinister calculations are possible. Is there, for example, a chance that the Administration has it in mind never to appoint a successor to Dr Press, not because it seeks to make a modest saving in the budget but because, as a matter of principle, it has decided that it does not want to be encumbered with such a person? Purists will quickly say that no modern administration would harbour such a thought. Has it not been amply demonstrated, ever since the end of the Second World War, that every administration needs a Science Advisor? Did not President Nixon's abolition of the President's Science Advisory Committee (not yet restored, even though Congress would like it back) show what harm can come to those who stab the research establishment in the back? One day, the calculation goes, there will be a constitutional amendment making the office of Science Advisor a part of the machinery of government, and from then on there will be no hesitation. Unfortunately, this simple calculation is wrong. It is probable that President Reagan has persuaded himself that if he cannot find a Science Advisor with all the virtues (distinction, discretion and an unwillingness to write memoranda unless asked), he will do without one. In that, he will be mistaken.

The case for having some kind of Science Advisor is subtle, administrative rather than an issue of principle. It is fashionable to say that science is so important that any president must have his own captive source, but that too stems from a mistaken view of what the world is like. The White House is not short of technical advice. Every government agency in Washington can supply a stream of memoranda to match whatever Dr Press's putative successor writes. The particular function of a Science Advisor in the White House is to hold the ring between the several warring agencies of government that ask contradictory (and impossible) tasks of every government — make unemployment go away, preferably by the encouragement of small business, make universities the powerhouses of innovation but less of a charge on the public purse, ensure peace by some technical device, but provide that if there is trouble in Central Europe, the United States will not be on the losing side. (A Science Advisor worth his salt will also be ready with opinions on whether the MX missile should be based in Utah or at sea, but may not again be required to advise, as in President Kennedy's time, on the best way to grow cranberries in Massachusetts.) In the last resort, however, what matters about the function of the Science Advisor in the White House is not the content nor even the quality of the advice rendered, but the fact of his or her existence. He or she is a lightning-rod, able to concentrate and then harmlessly to discharge the discontents of a powerful constituency. The constituency is not, however, all that powerful, these days, but short of funds and also of friends. An Administration with its wits about it would appoint a Science Advisor now, while it can still choose. If Mr Reagan delays much longer, he will find that he has less choice.

How not to run telecommunications

The British government seems well on the way to making a hash of its policy on telecommunications. Almost since last July, when the Secretary of State for Industry, Sir Keith Joseph, first spelled out the terms on which the old Post office monopoly would be

relaxed, the House of Commons has been struggling with a nasty compromise of a bill for the reorganization of the British Post Office. The proposal to separate the businesses of handling the mails and of managing telecommunications is sensible, if long

overdue. Most of the other provisions of the bill, especially those concerned with the new telecommunications business (trendily known as British Telecom) are unsatisfactory (see *Nature* 288, 424, 1980). Although British Telecom will no longer (if the bill becomes law) be able to decide for itself how to exercise all of its monopoly powers, these questions will be decided not by the balance of competition in a free market but by the Secretary of State and his civil servants, often with the connivance of British Telecom itself. Thus even on the relatively minor, or at least technical, question of what equipment telephone users may attach to their telephone circuits, the government has now agreed that recommendations by the British Standards Institution should be scrutinized (and no doubt quarrelled with) by British Telecom before being decided by the Department of Industry. That British telephone users will suffer from this fainthearted fudge is clear. Those principally concerned have so far failed to recognize that British Telecom will also be damaged.
